Case I.—Female, ten weeks old; the face livid; extremities cold; pulse small and feeble. From birth, the child had breathed with great difficulty. There had been hoarseness and spasm. The patient died three days after the consultation. At the autopsy, there was found in the larynx a papillomatous tumor, nearly filling up the glottic chink.

Case II.—Sixteen months old. She had suffered from birth with hoarseness and paroxysms of dyspnœa. At times there was great difficulty of breathing, and this was succeeded by an interval of nearly normal respiration. Spasm was especially noticed during and after crying. Only twice did the voice become entirely extinct. Shortly after coming under observation, whooping-cough was contracted, which was mild in character, and did not give rise to any alarming symptoms. During one of the paroxysms of coughing, a mass of reddish matter was expelled, which, upon examination, was found to consist of a papillomatous growth, covered with mucus. The tumor was of the size of a small bean (alentil). From this time, the hoarseness disappeared, and, with the recovery from the whooping-cough, there was no more disturbance of respiration.

Case III.—F.; was three years old, and of a good, healthy appearance. From birth, the cry was unnatural, hoarse, and croupy. There had also been paroxysms of dyspnœa. These attacks became more frequent and more severe as he grew older, and were believed to be caused by a congenital tumor in the larynx. In the spring of 1877, the dyspnœa became more constant.

It was thought best to perform tracheotomy, which was followed by complete relief to the dyspnœa, and the patient regained his general good health. During the next year there was no progress made in the effort to remove the tumor through the natural passages. In the meantime there had begun to develop spasms, though the canula was free, and so far as we could judge there was no obstruction in the trachea. These spasms finally became so alarming in their character that in March, 1878, thyrotomy was performed. A large papilloma filled up the larynx, it extended into the sub-glottic space, and seemed to make great pressure upon the walls of the larynx. It seemed probable that this pressure was the cause of the spasm, as there was no other explanation found. The patient did well for the next three days, when upon exposure he contracted pneumonia from which he died on the eighth day after the operation.

Case IV.—The voice was hoarse at birth, the cry was never natural. For some months before time of observation there had been almost constant dyspnœa with spasms of the glottis, which had latterly become alarming. The lips were blue, the pulse weak and small, there was considerable emaciation, and the struggle for breath was constant. Tracheotomy gave great relief to the distressing symptoms, but death followed within twenty-four hours. The post-mortem revealed a papillomatous tumor blocking up the glottis, leaving only a small opening through which respiration was accomplished.

Case V.—A well-grown male child, aged fifteen months, who since birth has had a rough, hoarse cry. Respiration was but slightly disturbed, but on careful observation the expiration was found to be slightly embarrassed, and on attempting to cry the voice became entirely extinct, and there was great difficulty in expiration. Laryngeal tumor, congenital, and probably papilloma, was diagnosed. As there was no urgent symptoms demanding immediate operative procedure, I advised that the child be taken home, and at some future time an effort be made for the removal of the growth. If in the meanwhile, the dyspnœa should become constant and urgent symptoms should arise, I advised that tracheotomy be performed.

About the first of June, 1880, I learned by letter from the parents, who were then living in the State of New York, that the tumor had evidently enlarged very much, and that breathing was so labored that suffocation was feared. By my advice, the child was taken to New York City, to consult Dr. G. M. Lefferts, from whom I learn that the patient, when seen by him, had dangerous dyspnœa, and urgent laryngeal spasms. By laryngoscopic examination, the complete blocking up of the larynx by papillomatous growth was recognized. Dr. Lefferts recommended tracheotomy at once, and explained to the parents the necessity of the thyrotomy at a future date. The tracheotomy was performed on the 10th of June; the child did unusually well until the 13th, when it developed the early signs of pneumonia, and died the next day.

At the autopsy, the larynx was found filled by papillomatous growths, fringing the whole of the vocal cords, lying at the base of the epiglottis, and in the inter-arytenoid commissure; only opening for the respiratory current posteriorly at the cartilaginous glottis, and very small.

In Case II., the spontaneous expulsion of the tumor is interesting. I have known similar results in adults. I have also seen several cases of papillomatous growths in the larynx, in which the patients ascribed the trouble to whooping-cough.

DR. KNIGHT said that in this connection he would like to state his own conviction in regard to the proper treatment of these papillomatous growths in very young children, in order to see how it might compare with that of other Fellows of the Association. In consideration of the gravity of the operation of thyrotomy, the great liability to permanent impairment of the voice, and the risk of the recurrence of the growth, he thought that the proper course to pursue in such cases is to insert a tracheotomy-tube, when urgent dyspnœa demands it; then wait for a not impossible spontaneous expulsion, or until the child gets old enough for operation per vias naturales.

DR. J. O. ROE said that the reading of Dr. Johnson's very interesting paper and the report of his cases recalled to him very vividly two cases of undoubted congenital growths of the larynx.

The first case he saw about five years ago. It was that of a child, two years of age, referred to him by Dr. Eli, Sr., of Rochester. From infancy, this child had had a very hoarse, croupy voice, and was unable to cry aloud. This condition continued to increase until he was one year old, when he began to have considerable difficulty in respiration, especially after exertion. From this period to the time when he saw him, the dyspnœa had not increased, and his condition had apparently remained stationary. He succeeded in making a laryngoscopical examination, which revealed a growth, evidently papillary in its nature, springing from one side of the larynx—he believed from the right side; he advised that tracheotomy be performed, but the parents preferred to defer the operation until it became more urgently called for. The family afterward moved away from the city, and he had not since heard from the child.

The second case was that of a child, about eight months old, which had not been able to cry aloud since birth, and had had frequent attacks of marked dyspnœa. As this condition was unassociated with any inflammatory trouble, the family physician brought the child to him for laryngeal examination. After several attempts, a growth was discovered in the upper portion of the larynx. It was advised that tracheotomy be performed at once, as the child was in imminent danger of suffocating. The operation was then performed.

The child progressed without accident; it has worn the tube since; and is now a stout, healthy child. In this case he also advised that the operation of removing the growth be deferred until it could be attacked per vias naturales, unless it should grow sufficiently to require operative interference before. In this respect he agreed with Dr. Knight, that the operation of thyrotomy should not be performed unless it be imperatively required by the condition of the patient.

DR. COHEN referred to the frequency of "colds" in early life, and to the well-known fact that papillomata frequently followed the catarrhal inflammations of the larynx in measles, croup, diphtheria, and whooping-cough, and he was rather inclined to believe that growths of this character that are really congenital are rare. He was opposed to the radical operation when not absolutely necessary; not so much on account of prospective injury to the voice, for that was a secondary matter to preserving the life of the patient, but he feared the cicatricial tissue of the divided skeleton of the larynx would materially interfere with the proper development of the larynx at puberty. He would also call attention to the fact indicated by the result of two operations in the paper that they are attended by a certain risk of pneumonia. He had long recognized this risk in all operations upon the cervical region, even when the air passage was not open, and was inclined to attribute it in part to the lowered temperature, to which the pneumogastric nerve and its ramifications are subjected. He therefore deemed it important that such operations should be performed in well-warmed apartments, and that great circumspection be used for several days after the operation.

DR. GEORGE W. MAJOR said that a clearly congenital case of laryngeal papilloma had not come under his observation; cases, however, had presented themselves so early in life that some interest might attach to a short narration of them. The first case, a child of two years, was referred for an examination on account of aphonia and dyspnœa. Active treatment was deferred until May 12, 1881, when a tracheotomy was performed. Since that date a tube has been worn continuously. In August, 1882, a quantity of papillomatous growths were expectorated, and the voice and breathing remained fairly good for at least two months, when they gradually became interfered with. A few weeks ago an examination showed extensive redevelopment of the growth, which was above the level of the cords. Another case was that of a child, aged ten months, with a hoarse voice from infancy, and occasional attacks of difficult breathing. It was seen for the first time at about its second month of life in consultation, and not again until a few days previous to its death. A tracheotomy was then urged, but it was so long delayed that when performed life only lasted twenty-four hours after it. On post-mortem examination, papillomatous growths were found in the larynx.

In regard to thyrotomy, he considered that even at the risk of permanent injury to the voice, it is a preferable operation to one through the cricoid cartilage, the acknowledged low vitality of which renders the operation liable to serious consequences, and he considered this tendency was much aggravated by the introduction of a tube between its cut surfaces and the resulting strain on its posterior plate.

DR. W. F. DUNCAN related the history of two cases of papilloma in children under three years of age. In both the diagnosis had been made with the laryngoscope. The parents of the first case refused to allow tracheotomy to be performed, and the child died from suffocation. The second case was operated upon and the tumor was removed. The child made a good recovery.

DR. WM. PORTER, of St. Louis, communicated a paper on

LARYNGEAL PARALYSIS FROM ANEURISM.

Laryngeal paralysis, he said, though a common sequence of thoracic aneurism, is not always the first evidence of the lesion. He presented notes of three cases in which the patients had, when first seen, no other subjective synopsis than those caused by the laryngeal condition.

The first had hoarseness and slight dyspnœa for two months, gradually increasing. There were no evidences of chest trouble, but by the laryngoscope could be seen the left cord fixed nearly in the median line. The opinion that there was pressure upon the left recurrent nerve was confirmed by the sphygmographic tracing of the left radial artery, which was characteristic of the lesion suspected. The tracing at the right wrist was normal. In a few months, the direct evidences of aneurism were easily found, and the affected cord receded to the "cardiac" position, showing that both adductor and abductor filaments of the recurrent nerve were pressed upon. The patient had since died of rupture of the aneurism.

The second case resembled the first in the more important particulars, but, although yet alive, has undoubted evidence of aneurism.

The third case, but recently seen, was one in which the hoarseness and change in voice were due to paralysis of the abductors of the right cord. No intra-laryngeal cause could be found, and as over the region of the ascending aorta near the arteria innominata, a bruit could be heard and slight thrill felt, an aneurism at this point was diagnosed. In this case the sphygmograph showed abnormal tracing at each wrist, which aided in fixing the location.

It is not the rule that an aneurism of this part of the aorta should press upon the right recurrent nerve unless of large size. The proof of aneurism, however, is almost complete, and there is nothing else as yet found to cause the laryngeal paralysis. The patient returned to his home in the South, and Dr. Porter has not been advised of any change in his condition.

In all of these cases the patients sought relief from the laryngeal condition not knowing of the thoracic lesion, and, in the first two, there was nothing in the chest to indicate it. We know that aneurism may exist without appreciable bruit or impulse, but these symptoms as well as increased area of dulness, are generally present when there is lesion enough to produce pressure upon the laryngeal nerve, and, in this, these two were also exceptional.

In all, as is generally true, the abductor filaments were first affected, but in the first as the pressure became greater, the adductor filaments became also impaired, and the changes in voice and respiration consequent were very interesting.

In these instances the sphygmograph gave valuable aid. It may not always give evidence of existing lesion, but where certain deviations from the normal tracings are obtained we can certainly trust its corroborative testimony. The importance of a laryngoscopic examination is self-evident in cases like those reported.

DISCUSSION ON PHOTOGRAPHING THE LARYNX.

DR. KNIGHT spoke in commendation of the work of Dr. French, and expressed great gratification at the improvement made since last year. Although the members probably were not competent to express a decided opinion upon the subject, or to discuss the method, he thought that the pictures submitted showed a great gain, and demonstrated that something really practical might ultimately come from photographing the larynx.

DR. CARL SEILER noticed a decided advance in the photographs over those of last year. As an amateur photographer himself, he could sympathize with some of the difficulties experienced by Dr. French, and suggested that possibly some improvements might be made in the apparatus, especially in the management of the drop-shutter.

DR. FRENCH said that he felt greatly encouraged by the remarks that had been made, which would stimulate both Mr. Brainard and himself to prosecute their experiments. With regard to Dr. Seiler's remarks about the apparatus, he thought that he would be able to introduce some changes which would improve it; he did not consider the apparatus perfect. Since he had begun this work he had received many suggestions which had greatly assisted him, and he hoped that by next year the photographs would be greatly improved, as well as the facility with which they can be taken.

Dr. Johnston asked for the reading of Dr. Porter's paper on "Laryngeal Paralysis from Aneurism," and offered a motion to this effect, which was not adopted by the Association.

At the close of the morning session, Dr. DeBlois exhibited some powder-blowers, made after the pattern of the Davidson atomizer. This construction permitted their being held in one hand while in use, thus allowing the other hand free to hold the tongue depressor. The delivery-tubes were of hard rubber, and could be turned either up or down as desired.

The Association then adjourned.

AFTERNOON SESSION.

DR. LOUIS ELSBERG read a paper on

REFLEX PHENOMENA DUE TO NASAL DISEASE.

Dr. Elsberg said that although some of the phenomena of his cases were not reflex, most of them were, and he considered it of clinical advantage to bring them all before the Association. Twenty years ago he observed a case of chorea in a child which had followed exposure to cold, and was relieved by treatment of coryza. Since then he had observed a number of other conditions which were attributable to nasal disease. These were principally (1) melancholia, (2) chorea, (3) reflex epilepsy, (4) neuralgia (especially supra-orbital headache and migraine), (5) gastric disturbances and diseased conditions of the upper digestive tract, as reflex pharyngitis, uvulitis, tonsillary enlargement, (6) uterine disorders, and affections of genito-urinary mucous membrane, (7) pain and disordered functions of the organs of sense, especially of smell and taste, but also of hearing and sight, (8) numerous affections of extra-nasal respiratory tract and organs of voice, among which are especially prominent the various alterations of the speaking and singing voice, laryngeal cough, glottic spasm, and bronchial asthma.

He recalled the fact that redness of the surface of the nose is often connected with nasal obstruction, and can be relieved by appropriate treatment of this condition. Among the curious instances of reflex disorder, he referred to a man suffering with chronic nasal catarrh, who always had an attack of sneezing during coitus.

DR. MACKENZIE emphasized the importance and insisted upon the great frequency of cough as a symptom of nasal disease. Clinical observation and experimental investigation had led him to the following conclusions:

1. That in the nose there exists a well-defined and sensitive area, whose stimulation, either through a local pathological process, or through an irritant introduced from without, is capable of producing an excitation which finds its expression in a reflex act or in a series of reflected phenomena.

2. That this area corresponds, in all probability, with that portion of the nasal membrane which covers the turbinated corpora cavernosa.

3. That reflex acts are produced by stimulation of this area, and are only exceptionally evoked when the irritant is applied to other portions of the nasal mucous membrane.

4. That all parts of this area are not equally susceptible to irritation, the most sensitive spots being, probably, represented by those portions of the membrane which cover the inferior half of the lower turbinated bone, and the erectile body on the septum immediately opposite.

5. That the susceptibility to irritation varies in different individuals; in some the slightest touch is sufficient to produce the reflex act, whilst in others it can only be produced after long-continued irritation.

That the reflex tract is limited to the above area is rendered probable by the following clinical facts.

1. That where reflex cough exists this is the area chiefly, if not solely, involved.

2. That the act may be induced by artificial irritation of the diseased structure.

3. That it may be dissipated by topical applications to, or removal of, the diseased membrane.

4. That polypi give rise to reflex phenomena only when they arise from or infringe upon the sensitive area.

5. That in cases where foreign bodies, such as pins, become impacted in the above area, reflex cough will sometimes occur, which latter is not observed when they lodge in the non-sensitive part of the nose.

DR. MACKENZIE had submitted a paper on the above subject to the Maryland Academy of Medicine, which would appear in the July number of the AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

DR. ROE said that the subject of reflex phenomena is a very interesting one; the more clearly the subject is understood, and the more thoroughly it is studied, the more readily will we be able to discover the cause of symptoms manifested in the derangements of one organ by disease located in another organ sometimes quite remote.

A very frequent illustration of the reflex derangement induced by nasal disease is seen in many cases of asthma. The association of asthma with nasal polypi is well known, but its association with hypertrophic turbinated tissue is quite often overlooked, particularly in those cases in which the nostrils are not greatly obstructed. By way of illustration, the speaker mentioned the case of a patient who consulted him last winter for severe and frequent asthmatic attacks to which he was subject, particularly at night. Examination revealed a mild form of chronic bronchitis, and in the nose considerable hypertrophy of the turbinated tissue over the inferior turbinated bone. In addition to other treatment, the hypertrophied tissue in the nose was removed, which gave almost immediate relief to the asthmatic attacks. Shortly after, he was obliged to take a car trip for three days. During the whole trip, he was quite free from any asthma or dyspnœa. Before this time he had not been able to travel by rail, particularly at night on sleeping cars, without suffering severely from dyspnœa, and being obliged to sit up all night and smoke, to be able to breathe with any degree of comfort. Many other cases could be cited in illustration of these phenomena of reflected symptoms of disease in the nose.

DR. SEILER said that he had reported in the *Archives of Laryngology* two cases of reflex irritation due to nasal disease, and gave the history of a case of chorea due to hypertrophies which was cured by the removal of the hypertrophies. He also mentioned the existence of cases, which he believed to be neurotic, in

which a sudden copious discharge from the nose, accompanied by sneezing, headache, and so forth, of a watery fluid, attacked the patient, and continued for some time, to disappear as suddenly as it had set in.

DR. BOSWORTH said that Dr. Elsberg had opened in this subject a wide and most interesting field for discussion. The speaker wished to refer to but a single point; it would be better, it seemed to him that in speaking of nasal catarrh, we should define the especial disease causing the catarrh; in spasm of the glottis, for instance, he had met with reflex symptoms in a number of cases of nasal disease, but it had been invariably due to a rhinitis atrophica, never to the hypertrophic form of the disease; in these cases the attack was of the most alarming character, and occurred in young as well as in adults; the youngest patient was six years of age; the oldest, a man fifty-five; the disease was entirely relieved, and no second attack occurred in any case, as long as the nasal membrane was kept thoroughly moistened.

DR. JARVIS said that a case of asthma caused by complete closure of the nares, by a deviated septum, gelatinous polypi, and turbinated hypertrophy, had come under his observation; the patient for several years had not omitted to rise early every morning and seek relief in going to the window for fresh air. Removal of the abnormal tissues, in a few weeks relieved the patient of the asthmatic attacks.

DR. CLINTON WAGNER then read a paper on

SMELL, HYGIENICALLY AND MEDICO-LEGALLY CONSIDERED.

He discussed the physical nature of odors, and pointed out the fact that many of them owed their characters to odorous particles held in suspension, while others were purely gaseous. The smells of various diseases, and different individuals were considered, and the fact that the sense of smell was analogous to that of sight in many respects; it can be cultivated and rendered keen by exercise, can be dulled by fatigue or over-use, and can be suddenly destroyed by overpowering odors. Where the sense of smell is lost by public nuisances, damages may be obtained from the municipality. The existence of odors is one important indication of the existence of certain causes of disease, which should be removed and destroyed.

DR. ROBINSON said he would make one or two remarks with regard to the subject of the paper. There was one fact which had always appeared to him to be of considerable importance, with regard to which there prevailed certain views which are erroneous; especially in the community at large there is a tendency to confound two things which are quite distinct—these are "deodorization" and "disinfection." These words are not synonyms, nor even are they correlated. He did not mean to say that odors are not of great value, as well from a medical as from a medico-legal point of view, nor to deny that it is not of importance to destroy or remove odor, but there is certainly an impression that by so doing we remove the sources of disease. He expressed the opinion, on the contrary, that the use of disinfectants do more harm than good; he might illustrate this in one or two ways; for instance, in this city, during an outbreak of smallpox, scarlet fever, or other epidemic, there is a popular power for the Board of Health to use carbolic acid freely; but when we bring strict analysis to bear upon this subject, and ask what we are doing when we use a disinfectant, let us at the same time inquire, in what does the contagion consist? Upon what is the carbolic acid supposed to act? Are we, in fact, rendering an area or atmosphere more healthy by its use? We must confess that we do not know in what the infection exactly consists; we do not know whether we are destroying its cause or not; indeed, there are many facts which prove the contrary, and when we think that we are removing the cause, we are simply covering it, and perhaps permitting extension of disease. He cited a statement to the effect that, during an epidemic of yellow fever in New Orleans, in that part of the city where carbolic acid had been used most freely, the epidemic prevailed most extensively, and was more fatal. Must we not conclude that wherever we remove a bad odor, we do not necessarily act upon the noxious agent or contagium of the disease. He believed that we do not exactly know in what the contagium of smallpox, yellow fever, and similar diseases really consists. Some of the Fellows might take exception to this statement, as much attention had been attracted to this subject by the journals; but we really do not know the noxious agent, although we have learned something of its habitat and its means of communication. We have noticed that where sickness of an epidemic character is found in a house, physicians are very apt to go to the sewer connections, and if they find an odor, they say sewer gas, and conclude this is the reason; and yet, in the tenement-houses sewer gas is present all the time, and yet the relative mortality or sickness is not affected thereby.

DR. CHAMBERLAIN said that the popular idea that all bad odors are dangerous is erroneous; the important element is the germ of the disease, and upon the presence or absence of that the danger to health depends; a bad odor may, however, give warning of danger. Thus in a workshop one shop is especially unhealthy, by reason of certain offensive odors which exist near it; cases of slight illness were frequent and typhoid fever found many victims among the operatives. A Quaker surgeon had said "a strong smell is healthy." He believed that as physicians we have nothing to do with smells, at least in the hygienic point of view, although, when found in nature they lead us to seek for putrefaction, yet the same odor may be made artificially in the laboratory without putrefactive changes.

As long as the odor merely conveys to the brain the information as to its source and nature it does no harm, but when it carries at the same time the germs of disease into the system it is dangerous. So far as we know these diseased germs they have no smell, and, therefore, as far as the mere character of smell is concerned we have nothing to do with odor.

DR. WAGNER in closing the discussion, stated that he thought that he had been misunderstood by Dr. Robinson; he had not suggested that noxious odors should be removed by disinfectants, but that the cause being ascertained remedies should be applied with a view of removing it. In regard to Dr. Chapman's remark that bad odors were of no consequence, and that they indicated nothing, he would say that if the warning given by foul odors in the Hoboken School had been heeded, many lives would have been saved.

DR. HARRISON ALLEN, of Philadelphia, then presented some remarks on

ASYMMETRY OF THE NASAL CHAMBERS WITHOUT SEPTAL DEVIATION.

The subject of asymmetry of the nasal chambers, he said, can be considered from two points of view, viz., from the changes in proportion due to deflection of the nasal septum; and second, from the standpoint of inequality of the chambers themselves in subjects in whom the nasal septum is straight. The group last mentioned will form the basis of the present communication.

As a result of observation of ten examples of crania, selected from the anatomical cabinets of Philadelphia, it may be concluded that a difference in the diameters of the posterior nares can be detected. In the living

subject, the writer has reason to believe that the same asymmetry in the posterior nares can be discerned, and that, at least in the persons of those reporting for the relief of catarrhal affections, the number exhibiting such asymmetry is much larger than would appear from the examination of crania. As the result of clinical study in this direction, extending over the last two years, he concludes that nasal obstruction may be limited to one side of the nasal chambers only; and that such tendency to obstruction may be due to the congenital narrowing of this passage, the nasal septum remaining without deflection.

It is not necessary at this time to attempt an elaborate description of this variety of conformation of the nasal chambers, with its clinical applications, but simply to call attention to a fact which appears to have escaped observation, or, at least, to have received so little attention in the minds of observers as not to enter into questions of diagnosis and prognosis of nasal disorders. It is quite evident that imperfect nasal respiration, due to the above-mentioned cause, cannot be relieved by any operation on the septum, as these operations are at present defined, and that no operation short of drilling away the entire inferior turbinated bone will be likely to afford relief.

It is interesting to remark that among the crania exhibiting the above peculiarities, the best-marked examples were found in the skulls of idiots, in whom marked asymmetry of the cerebral fossæ was also seen. It is not at all unlikely that the real solution of the subject of congenital asymmetry, without septal deflection, is to be found in the peculiarities of development of the cerebral hemispheres themselves; and that the study of this subject can not be separated from the general subject of bilaterality; that is, the general subject of right and left symmetry as controlled by the cerebral nervous system.

DR. DELAVAN said that the subject which Dr. Allen had brought to the attention of the Society in such an able and interesting manner was one which was new to most of the Fellows; it was one in which Dr. Allen was the pioneer, for in his published works and in his private investigation, he with Zuckerkandl had probably given the subject more attention than any other living observer. The lecturer had struck at the root of nasal difficulties. For several years past great advances had been made in the pathology and treatment of the nasal cavities. Unfortunately, however, most investigators had begun at the wrong end of the question, and instead of beginning at the foundation had confined their attention to the superficial structures. It is simply impossible to relieve many cases of nasal obstructions, and the conditions arising therefrom, merely by medical measures. In many instances surgical treatment would be necessary to accomplish a thorough and radical result. The speaker's own investigation had been in the direction of Dr. Allen's, and he had been greatly interested and pleased by the suggestions which the latter had given. The great importance of the recognition of these conditions of nasal malformation is, of course, with regard to their prognosis and treatment. Many of them, he believed, could only be relieved by severe surgical measures.

DR. RUFUS P. LINCOLN, of New York, then read a paper on the

RESULTS OF THE TREATMENT OF NASO-PHARYNGEAL FIBROMA, WITH DEMONSTRATION OF SUCCESSFUL CASES, TOGETHER WITH A TABLE OF SEVENTY-FOUR OPERATIONS BY DIFFERENT SURGEONS.

The neccessity for treatment, he said, arises from the course of the disease which, if not interfered with, causes great suffering, deformity, and destruction of the life of the patient.

The object of treatment is: 1. The thorough removal of the growth, with the destruction of all diseased tissue at the place of origin. 2. Avoidance so far as possible of accidents incident to operations on the naso-pharyngeal region. 3. To secure the result with the least external disfigurement. To illustrate the different methods of treatment, and their relative merits, a table of seventy-four operations by different surgeons is presented, together with three cases cured by Dr. Lincoln, by means of the galvano-cautery, écraseur, and subsequent treatment with the galvano-cautery. The galvano-cautery is shown so far to have given a greater percentage of successful results, and this method has the further advantage of being simple, less dangerous, and leaves no deformity.

DR. JARVIS said that last year he removed a large myxofibroma from the nares of a young man. The tumor was attached above the left post-nasal arch. It projected forward into the left anterior naris, extended for some distance into the right nasal cavity, and almost completely occluded the naso-pharynx. He operated twice, removing the entire polypous growth. His écraseur was employed. Although the severe strain bowed the instrument, the patient only complained of a toothache and the tedium of the operation. He carried the loop around the growth through the pharynx, afterward bringing the wire through the nose. Four hours were occupied by the operation, and, although the instrument pulsated like an artery, there was no blood lost. Four months after the operation there was not a vestige of the growth to be seen. The division of the tumor through its densest portion without pain and hemorrhage demonstrated a safe and easy method for removing large naso-fibroid tumors piecemeal, without resorting to the more formidable operations of general surgery.

DR. A. H. SMITH described a case in which he had removed a fibroma springing from the vault of the pharynx, and having a length of between two and three inches, and a thickness of one inch. The instrument employed was the Jarvis snare, the wire being passed from the mouth out through the anterior nares. The wire broke at the last moment, but strangulation had been effected, and the growth afterwards sloughed. A subsequent operation became necessary a few weeks later on account of the rapid growth of the pedicle. After the second removal, the stump was touched three times a week with perchloride of iron; there is now, four weeks later, only a small papule remaining to indicate the location of the pedicle.

DR. SEILER said that he had seen a number of cases of the kind referred to by Dr. Lincoln. In one patient, where the posterior nasal chambers were blocked up by the growth, which, with the finger he could recognize as having undergone cartilaginous changes, he had succeeded in removing the growth with a wire snare, and had afterward applied the galvano-cautery. Although he was told by the patient that the growth had been previously removed about nine months before, while in the South, he had not seen since the last operation any evidence of recurrence. In another case he had great trouble in applying the snare, as the loop slipped off again and again. He finally, in the course of several weeks, removed the growth piecemeal; it weighed over four ounces. Another patient, an old man seventy-four years of age, had come to him for treatment, but as he was from the country he was obliged to let him go to a hospital. However, he removed a portion of the growth, which enabled the man to breath more freely, and he had no doubt that he could have eventually removed it entirely by the method which was successful in the preceding case. The attending surgeon at the hospital attempted to re-

move part of the maxilla two days later, but the patient died while on the table under the influence of ether.

Dr. Ingals had operated upon three cases of this kind during the last three months, although in only one was the character of the growth determined by microscopic examination.

In this case he had removed it with the galvano-cautery, and the tumor did not return; it was not very large, however—about the size of an ordinary black walnut, about two inches in diameter. In a second case he had great difficulty in surrounding the base of the tumor with the wire of the écraseur; finally, by introducing a wire in a soft catheter through the nares into the mouth, behind the soft palate, and attaching a thread to it, he succeeded in surrounding the growth with the wire. He had used the handle of Shurley, as modified by Bosworth, for holding the wire, but found some difficulty in using it with the battery, as it was short-circuited through the little wheel at the side. By substituting a lead-pencil in place of the metal wheel he succeeded in removing the growth, but thought that he possibly removed it too fast, for although there was not much pain there was excessive bleeding; the hemorrhage was finally stopped after twenty minutes, and he learned from the attending physician that the patient fainted two or three times during the evening after the operation.

Dr. Bosworth thinks that the Association owes a debt of gratitude to Dr. Lincoln for bringing before it this splendid series of cases, successfully treated without resorting to the severer operation generally followed by surgeons; personally, he felt indebted to him for the superb demonstration.

He would like to say that he had heard during the discussion about myxo-fibroma, fibroma, and polypi, and he would like to understand what was meant by these terms. According to his opinion, a fibroma is never a polyp, and a polyp is never a fibroma.

Dr. Smith asked permission to call attention in the use of the galvano-cautery écraseur of the great advantage of drawing the temper of the wire for several inches at its ends for the purpose of facilitating subsequent manipulation.

Dr. Lincoln, in closing the discussion, said that he had nothing to add to what had been stated in the paper. He simply wished to bring these cases before the Society, and to call its attention to a plan of treatment in preference to the ordinary one of removing the superior maxilla. The operation which he proposed is much safer than the old one, after which nearly one-third of the cases died, as shown by the statistics for the last fifteen years. Some of the speakers had referred to the difficulty in attaching the wire over these growths. It is true that it requires some patience and perseverance, but with these all its difficulties can be overcome.

The President introduced to the Association Dr. Holland, who had been working in Mr. Edson's laboratory, who wished to exhibit

AN ILLUMINATING APPARATUS FOR EXAMINING THE UPPER AIR-PASSAGES

Dr. Holland said that he regretted that he had to exhibit the instrument while it was still in an imperfect state, but he could show that with the assistance of Mr. Edson's physician, he had been successful in adapting the electric light to a glass tube for the purpose of illuminating cavities of the body. The instrument which he exhibited, was a glass tube enclosing the carbon filament, and covered by a shield for the greater portion of its extent. He stated that it works well with a small power, only two Smee cells being required. The principle is simply that of direct illumination of the cavity itself, without the use of a mirror. The defect in the instrument was that the shield did not extend far enough forward. The glass tube is larger than necessary, but is made so in order that it may not heat up so as to become uncomfortable to the patient. He stated that for himself he felt much encouraged at its success as an illuminator.

The President stated that directly after the close of the meeting, Dr. Lincoln had some cases which he would exhibit to the Fellows:

The meeting then adjourned.

In the evening, the Association was entertained by the President, Dr. Lefferts, at a theatre party at Wallack's, followed by a supper at Delmonico's.

May 23d, Third Day.—Morning Session.

Dr. J. Solis Cohen, of Philadelphia, reported the essential details of a

CASE OF THYROTOMY FOR MORBID GROWTH, WITH SUBSEQUENT DEVELOPMENT OF EPITHELIOMA IN THE CUTANEOUS CICATRIX, BUT WITHOUT INVOLVEMENT OF THE INTERIOR OF THE LARYNX.

The patient, a practising attorney, aged 63 years, had been hoarse for some two years. Laryngoscopic inspection revealed a morbid growth at the anterior portion of the ventricle and vocal band of the right side. Its rapid development during a few weeks seeming to contra-indicate the propriety of intra-laryngeal efforts for its extirpation, the larynx was divided anteriorly, and the tumor removed.

Two years later a tubular epithelioma was removed from the tissues extending to the right wing of the thyroid cartilage, and two months after that another from the left side,

The suspicious appearance of the cutaneous parts in front of the larynx led to the removal of the entire tissue, which was found infiltrated with epithelioma, and the transferrence of two flaps from the chest to cover in the parts. Recurrence took place in the flaps a few months later, and the patient died from exhaustion six months after the last operation. During all this time the interior of the larynx remained healthy and the voice good. He attributed the development of the cutaneous epithelioma to irritation of the cicatrix from the shirt collar-band, notwithstanding the fact that a very low and loose band had been habitually used to avoid contact with the cicatrix.

Dr. F. H. Hooper, of Boston, read a paper on

EXPERIMENTAL RESEARCHES ON THE TENSION OF THE VOCAL BANDS.

He treated the subject under two subdivisions, viz.:

(*a*) The action of the thyro-cricoid muscle.

(*b*) The action of the expiratory blast of air.

The experiments were performed in the physiological laboratory of the Harvard Medical School, in conjunction with Prof. Henry P. Bowditch; and diagrams and figures reproduced from the original tracings and drawings by the photo-electrotype process were exhibited.

In treating of the action of the thyro-cricoid muscle, Dr. Hooper gave a historical review of the subject, showing the wide diversity of opinion regarding the action of the important tensor, commonly but incorrectly called the crico-thyroid muscle. His experiments force him to reject the theory, generally received, that its function is to tilt the thyroid cartilage downward and forward on the cricoid; and they prove conclusively that its action is to draw the cricoid cartilage forcibly upward on to the thyroid, the latter remaining practically fixed.

As regards the action of the expiratory blast of air, he said hitherto the action of the air-blast as a tensor of the vocal bands has been recognized as producing its effect (as any current of air might stretch an elastic

membrane) merely by its force in coming in contact with them. His experiments establish the fact that in addition to the general rise of the whole larynx, as in singing high notes, the pressure of air causes an excessive and independent upward movement of the cricoid cartilage on to the thyroid, of which no mention, to his knowledge, has heretofore been made.

The facts demonstrated by the experiments made by Dr. Bowditch and himself, justify the following conclusions:

1. The cricoid cartilage is the most movable part of the laryngo-tracheal tract.

2. The thyro-cricoid muscle, according to its physiological action, should be described as arising from the thyroid cartilage, and inserted into, and giving motion to, the cricoid.

3. The air-blast, in virtue of the mechanism set forth, is a direct and important longitudinal tensor of the vocal bands.

THE PRESIDENT said that he felt that he must very cordially congratulate Dr. Hooper upon the important laboratory experiments he had made, and upon the great interest of his paper. He thought that the Fellows of the Association would hardly feel warranted in discussing the communication without having had the opportunity of giving it the attentive reading that it deserved, and would perhaps, therefore, prefer to wait until it appeared in print.

DR. HARRISON ALLEN said that he believed that Darwin in his great and now monumental work on the *Origin of Species*, made use of the term "The Imperfection of the Geological Record," in speaking of the great difficulty that biologists have experienced in endeavoring to make use of this record in any exact way in framing deductions which were not in themselves geological. While listening to Dr. Hooper's paper, it occurred to him that a similar phrase might be used appropriately in reference to anatomy; we may speak of the "Imperfections of Anatomical Record"—in considering many questions in human anatomy as this science is conventionally taught. The speaker believed that we are only too apt to look upon anatomy as a closed subject, that all the important questions with regard to the anatomy of the human body had been studied so far that it would not be profitable to pursue the subject further. This is the prevailing opinion of students prior to graduation, and too often is shared by teachers of anatomy. He thought, that it was only necessary to listen to such papers as this of Dr. Hooper's to be convinced that little exact knowledge is in our possession on the subject of synergic muscular action. Here is a little muscle in the neck, readily exposed and easily studied, and yet it has just been shown that we have had quite inadequate conceptions of the work done by it. Too often have authorities pronounced upon the action of a muscle from its form and relations; because the thyro-cricoid (generally spoken of as crico-thyroid) has a broad base from which its fibres converge to a point, as is the case indeed of the adductor-magnus, it had been hastily assumed that the broad portion was the origin and the narrow attachment the point of insertion, as in the deltoid muscle. From superficial observation its action had thus been concluded to be that described in the text-books. He thought that what Donders and Helmholtz had done for the eye, and Helmholtz for the ear, researches of the character instituted by Dr. Hooper would do for the larynx.

While listening to the paper the remarks which Hilton, of London, in his book on *Rest and Pain*, had made upon this subject had come into his mind. Hilton considered that the pneumogastric nerve controls the movements of the laryngeal muscles very much in the manner that a violinist plays upon his instrument. The motor impulse is first carried to the extrinsic thyro-cricoid muscle—as the finger of the violinist makes tense the strings of his instrument—which tightens the vocal cords; and that after this is accomplished, the motor impulse extends along the recurrent laryngeal nerve to the intrinsic laryngeal muscles to control the formation of sounds

Dr. Allen thought that the phenomena of the expiratory blast, as described by Dr. Hooper, were in like manner reflex in character, and were to be explained by the exciting afferent impulses along the sensory filaments of the superior laryngeal nerve, and creating efferent impulses which were sent along the motor branch to the thyro-cricoid muscle.

DR. LANGMAID endorsed the President's remark, that intelligent criticism of such a paper as that which Dr. Hooper had just read was impossible without further opportunity for its consideration; but he wished to say that it met with his hearty approval, and that it seemed to him that for the first time there had been given an intelligent and precise explanation of some of the phenomena of tension of the vocal cords and voice-production.

While he believed that all notes of the singing voice should, theoretically, be produced without any increase in the force of the wind-blast, it is easy to see from Dr. Hooper's exposition of the action of the expiratory breath upon the movement of the cricoid, and the consequent increase of tension, exactly how the blast of air is called in as an assisting, supplementary factor in the production of intense high notes. Secondly, his explanation of how the concentration of the expiratory blast in the larynx, the chink of the glottis being closed, causes a certain amount of tension of the cords, reveals the reason of its frequent use by vocalists, as it does also the frequently observed fact that a singer whose conversational tone is hoarse, may still have a clear singing voice; because, as indeed was already well known, this concentration of air in the larynx constantly takes place in the singing voice on account of the continuous production of vocal sounds.

DR. HOOPER, in closing the discussion, said that he was sure that Prof. Bowditch would be as much gratified by the interest which the Fellows of the Associatien had taken in his experiments as he was himself. It would be impossible to carry on such experiments single-handed, and he felt it proper to say that if the distinguished Professor of Physiology at Harvard had not himself taken especial interest in the study of the larynx, and devoted his time and ingenuity to the details of the experiments, it would have been impossible for him to have presented the paper which he had the honor of reading before the Association.

DR. BEVERLY ROBINSON then read a paper on

AURAL COMPLICATIONS OF INFLAMMATORY CONDITIONS OF THE NOSE AND THROAT.

He referred to the importance of aural complications in diseases of the nose and throat, and divided the subject into ear disorders complicating acute throat and nose diseases; and secondly, those complicating chronic affections of this character. The morbid process in acute cases not uncommonly extends to the middle ear, but he had never seen suppurative disease of the ear following ordinary catarrhal inflammation of the nose. Disorders of the ear, therefore, should receive attention in diseases of the upper air-passages. The fact that such disorders are apt to follow diphtheria, variola, scarlet fever, measles, and similar exanthemata due to catarrhal inflammation of middle ear might, he thought, be explained, at least in some cases, by the direct extension of the inflammation, as they are more likely to occur when the throat disease had been unusually severe.

In chronic obstruction of the air-passages, he referred to the necessity of treating the primary disease in the nose or pharynx in order to relieve any attendant symptoms of middle-ear disease, and insisted upon the value of rhinoscopic examination.

Dr. Mackenzie called attention to the influence of reflected irritation from the turbinated tissues of the nose as a factor in the production of middle-ear congestion and catarrh. In a certain proportion of cases occurring in his clinical experience, he had noticed congestion of the drum-head and other symptoms referable to middle-ear disease which could not be explained on any other hypothesis, and which were dissipated by topical treatment of the local nasal disease. He had, furthermore, succeeded in producing congestion of the membrane of the tympanum, pain, etc., by artificial irritation of the nasal mucous membrane. Cases now and then present themselves which, from failure on the part of the physician to recognize this relationship, and in the absence of well-marked nasal disease, are treated as hysterical, and their ailments are believed to be imaginary. He thought that the recognition of these facts, and the proper appreciation of their importance, would materially aid in the diagnosis and treatment of this heretofore obscure class of affections.

Dr. Jarvis said that especial attention should be given to the part played by turbinated hypertrophies, gelatinoid polypi, and to the deviated septum, in the production of aural difficulties. It is not necessary that the orifice of the Eustachian tube should be occluded by the growth, pressure upon the edge of the tube may mechanically interfere with audition by disturbing the pneumatic equilibrium of the middle ear. Deviation of the septum may also occasion deafness by a coexisting distortion of the nose preventing the efflux of secretion, and favoring the extension of inflammation into the middle ear. The ease with which these deviations can be removed would warrant their immediate excision.

Dr. Robinson said, in closing, that he agreed entirely with Dr. Mackenzie, and believed that his remarks were correct. He had, some weeks ago, been made aware of the importance of this reflex nervous influence upon the ear from nasal disease, but not in sufficient time to incorporate it in his paper. He thought, however, that a certain number of cases would find their true explanation in this way.

Referring to Dr. Jarvis' remarks, he stated that he formerly had shared his opinion as to the effects of mechanical obstruction of the upper air-passages upon the hearing of the patient, but had recently seen some cases which had led him to doubt its applicability. In a woman under his care at the New York Hospital, although the nose and pharynx were almost completely obstructed by polypoid growths, still her hearing was good. Perhaps, in view of cases like these, he might conclude that Dr. Jarvis was attributing more importance to such deviations as a cause of inflammation to the middle ear and disorders of hearing than experience justified.

Dr. D. Bryson Delavan then read a paper on

THE LACUNÆ TONSILLARUM.

After calling attention to the importance of the tonsillar crypts in the general economy of the organ, the lecturer went on to describe the lucunæ tonsillarum as a series of depressions formed by the reduplications of the oral mucous membrane and their contained adenoid tissue, which constitute the organ known as the tonsil. Their number is variously estimated at from eight to eighteen. Many of them are spacious in extent, and they commonly penetrate deeply into the substance of the gland, sometimes almost reaching to its hilum. There are also in the interior of the tonsil single larger cavities, each one of which includes several follicular folds, and procures their common discharge at the periphery. By this arrangement, the actual superficial extent of the tonsil is greatly increased. To this fact the speaker directed particular attention.

In common with the rest of the buccal cavity, the surface of the human tonsil is invested with a thick covering of pavement epithelium, which rests upon a delicate endothelioid basement membrane. Following this is a tolerably compact mucosa, formed of interlacing bands of connective tissue, and containing many connective-tissue corpuscles. Occasionally, the adenoid tissue extends so near to the surface of the organ that it penetrates the mucosa, and, here and there, actually encroaches upon the epithelial layers. In the walls of the crypts this encroachment is especially marked, the more so as the bottom of the crypt is approached. In other words, the epithelial and subepithelial layers, thick at the periphery, become rapidly more delicate the deeper we trace them down the crypt wall, until, toward the lowest depth of the lacuna, they generally disappear. This disappearance is probably due to the attenuation of the mucous membrane in this locality, and its consequent liability to rapid post-mortem decomposition, and to mechanical injury in the preparation of the section.

This *unusual destructibility* is *another* point worthy of attention, for it, together with the point before mentioned, namely, the increase in the superficial extent of the tonsil caused by the crypts, constitutes a factor of the greatest importance in the pathology and the treatment of diseased conditions of the gland.

First, in its pathology, it is evident that any morbid condition which may affect the surface of the tonsil may also, as a rule, extend into the crypts, and thus add greatly to the amount of irritation apparently present in a given case. Moreover, the delicate nature of the lining of the crypt wall would facilitate the absorption of matters retained in the crypt, and this, together with the intimate connection ot the tonsil with the lymphatic system would manifestly expose the patient to the danger of general infection in certain conditions of local poison, as, for instance, in diphtheria, in the sloughing ulcers sometimes seen upon the tonsils of hospital attendants, and in erysipelas.

The effect of irritation of the crypt upon the whole tonsil is a matter of common observation in cases where the crypt has been distended by cheesy accumulations, by tonsillar calculi, or by retained pus.

The writer had recently seen a case in which the latter condition was unquestionably accountable for a well-marked swelling and tenderness of the cervical lymphatics, and a similar case had been reported to him by Dr. Albert H. Buck.

As to the matter of treatment, however, these very anatomical conditions before mentioned offer possibilities for the relief of disease which have but rarely been appreciated or utilized. Instead of merely painting over the well-protected surface of the tonsil, let the medicament be applied thoroughly to the delicate wall of the interior of the crypt. Not only will a far greater extent of surface be reached, but also the effect upon the gland will be much more profound from the great ease with which the application will be absorbed.

The objection may be urged that to make such an application to the tonsil of a child, or even to an adult tonsil of normal size, would be impracticable. It should be remembered, however, that morbid conditions of the tonsil are almost invariably accompanied by hypertrophy, and that the larger the tonsil the larger will be the crypt, and this, together with the insensitiveness of the organ which exists in many instances,

will render the operation easier than might be supposed. By this plan three general varieties of treatment may be employed, the disinfectant, the astringent, and the cauterant. The crypt should first be cleansed by means of a bit of absorbent cotton upon a fine probe, or by a stream of water from a curved syringe, and the application then made. Dr. Lincoln had for a long while advocated the use in this manner of a strong solution of iodine and chloride of zinc, and he and others have also used nitrate of silver, fused upon the end of a probe. For this purpose the writer has found it exceedingly convenient to apply the fused nitrate to the end of a small splinter of wood. This can readily be grasped in any good forceps, and when once used it can be thrown away. The measures suggested can nowhere be so well utilized, probably, as in those troublesome cases of hypertrophy of the tonsil in which excision is for any reason impracticable. No stronger argument could be brought forward, however, in favor of excision of a hypertrophied tonsil than the anatomical points referred to in this article. The conditions in which the general measures referred to will be applicable will readily suggest themselves.

OFFICERS FOR 1883-84.

The nominations for officers of the Association for the coming year, as presented by the Nominating Committee, were read.

On motion, the Secretary was authorized to cast the ballot for the Association, and the President declared that the following were unanimously elected

President.—F. H. BOSWORTH, M.D., of New York.

Vice-Presidents.—S. W. LANGMAID, M.D., of Boston; S. JOHNSON, M.D., of Baltimore.

Secretary and Treasurer.—D. BRYSON DELAVAN, M.D, of New York.

Council.—ANDREW H. SMITH, M.D., of New York; HARRISON ALLEN, M.D., of Philadelphia; MORRIS J. ASCH, M.D., of New York; BEVERLEY ROBINSON, M.D., of New York.

TIME AND PLACE OF MEETING.

On motion, the recommendation of the Committee was adopted that the next congress of the Association shall be held in New York City, on the third Monday in May, 1884.

Upon adjournment, the PRESIDENT invited the attention of the Fellows to an exhibition of instruments.

(The Proceedings of the *concluding* afternoon session will appear in our next issue.)

NEWS ITEMS.

THE MARINE-HOSPITAL SERVICE AND THE EPIDEMIC FUND.—The Secretary of the Treasury has authorized the Surgeon-General of the Marine-Hospital Service to make requisition from time to time for such sums as may be necessary to carry into effect the purpose of the last appropriation for the prevention of the spread of epidemic diseases.

STATE MEDICAL SOCIETY OF ARKANSAS.—The Eighth Annual Session will be held in Little Rock, on Wednesday, May 30th, at 10 A.M.

OHIO STATE MEDICAL SOCIETY.—The Thirty-eighth Annual Meeting of the Ohio State Medical Society will be held at Cleveland on June 5th, the same day on which the American Medical Association meets. The Society will be called to order in the "Tabernacle" on Ontario St., at 9 o'clock.

The Committee of Arrangements of the American Medical Association having formally extended to the Ohio State Medical Society, through its Committee of Arrangements, an invitation to arrange for a single session, at which only necessary business shall be transacted and then to adjourn and to have the members become members by invitation of the American Medical Association, the Committee of Arrangements of the State Society will, in their report, recommend an acceptance of the invitation.

NEW JERSEY STATE MEDICAL SOCIETY.—The One Hundred and Seventeenth Annual Meeting of the Medical Society of New Jersey will be held in Atlantic City on the second Tuesday in June, 1883, at four o'clock P.M.

HEALTH IN MICHIGAN.—Reports to the State Board of Health, for the week ending May 12, indicate that diphtheria, neuralgia, influenza, remittent fever, and intermittent fever have increased, and that diarrhœa, and rheumatism have decreased in area of prevalence.

Including reports by regular observers and by others, diphtheria was reported present during week ending May 12, and since, at eleven places; scarlet fever, at sixteen places; and measles, at thirty-one places.

OBITUARY RECORD.—Died in New Orleans, on May 21st, JOHN DICKSON BRUNS, M.D., in the 47th year of his age.

Dr. Bruns was a native of Charleston, S. C., and received his medical education at the South Carolina Medical College, from which he was graduated in 1857. He entered the service of the Confederate States as surgeon, and remained until the close of the war, when he went to Europe, in order to prosecute his medical studies. In 1866 he was called to the chair of physiology in the New Orleans Medical School. He was the editor and proprietor of the *Charleston Medical Journal and Review* from January, 1858, to January, 1861, and during that time was Professor of Physiology in the Charleston Preparatory Medical School. He was adjunct professor of practice in the South Carolina Medical School in 1866; professor of physiology and pathology in the New Orleans School of Medicine from 1866 to 1870, and in 1874 was made professor of the theory and practice of medicine in the Charity Hospital Medical College, New Orleans.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 14 TO MAY 21, 1883.

BURTON, HENRY G., *Captain and Assistant Surgeon.*—Now awaiting orders at St. Paul, Minn., assigned to temporary duty at Fort A. Lincoln, D. T.—*Par. 1, S. O. 83, A. G. O., May* 15, 1883.

MACAULEY, CARTER N. B., *First Lieutenant and Assistant Surgeon.*—Assigned to duty at Fort Bennett, D. T.—*Par. 2, S. O. 83, Department of Dakota, May* 15, 1883.

PORTER, J. Y., *Captain and Assistant Surgeon.*—Assigned to duty at Fort Davis, Texas.—*S. O. 49, Department of Texas, May* 14, 1883.

WILSON, GEORGE F., *First Lieutenant and Assistant Surgeon.*—Upon being relieved as Post Surgeon at Fort Townsend, W. T., assigned to duty at headquarters, Department of the Columbia.—*Par. 2, S. O. 64, Department of the Columbia, May* 10, 1883.

WILSON, GEORGE F., *First Lieutenant and Assistant Surgeon.*—To report to First Lieutenant Frederick Schwatka, Third Cavalry, for duty in connection with explorations in the Department of the Columbia.—*Par. 3, S. O. 64, Department of the Columbia, May* 10, 1883.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. XLII. SATURDAY, JUNE 2, 1883. NO. 22

ORIGINAL LECTURES.

ON SUBINVOLUTION OF THE UTERUS.

A Clinical Lecture, delivered at the Cooper Medical College, San Francisco.

BY CLINTON CUSHING, M.D.,

PROFESSOR OF GYNECOLOGY.

GENTLEMEN: The patient before us this morning is of interest to you, not so much because she is suffering from any unusual or novel affection, but on the contrary, for her troubles are among the most common that you will meet in the treatment of the diseases peculiar to women, and it is because they are so common, and that we have several distinct affections combined in this case that she has been brought in here for our consideration.

I will now ask her a few questions, in order that you shall get her history fairly before you.

"How old are you, madam?"

"Thirty-five, sir."

"How many children have you had?"

"Seven."

"Have you had any miscarriages?"

"No, sir."

"Is your monthly sickness regular?"

"No, sir; it comes on sometimes once in six weeks, and sometimes once in three months, and I lose but little blood."

"Do you have any leucorrhœa or pain?"

"Yes; I have a hot feeling, and pain in the top of my head most of the time, and a good deal of pain under my left breast, and constant backache between my hips, and I have the whites all the time, and I cannot walk or stand upon my feet long without pain."

"How long have you been suffering from your present troubles?"

"Since the birth of my sixth child, six years ago."

The further history of the case shows that she is suffering from obstinate constipation, that her digestion is impaired, and that she sleeps badly at night. So far as can be learned, she has not had pelvic peritonitis or cellulitis. Upon examining her, we find that the uterus is enlarged, the cavity measuring three and one-half inches in depth; the uterus is retroverted, the fundus lying upon the rectum, and the cervix pointing towards the ostium vagina.

There is a bilateral laceration of the cervix, the posterior lip is rolled out, much thickened, and enlarged, covered by profuse granulations, and studded over with small cysts, the whole bathed in a profuse muco-purulent discharge.

In addition, we find that when she is in the semi-prone position, and with two fingers in the vagina, we try to push the fundus up from its unnatural place, that the body of the uterus and the utero-sacral ligaments are quite tender to the touch, preventing the reposition of the displaced organ without causing marked distress.

You will please notice that she is pale and anæmic, and has the expression of one who has undergone much suffering, both bodily and mental; for, in cases of this kind, it is not alone mere physical pain that we have to deal with, but a condition of the mind and nervous system that has become morbid, and that frequently gives us more trouble to relieve than the purely local affection.

The diagnosis here then is, first, subinvolution of the uterus following confinement, with retroversion, bilateral laceration of the cervix with eversion of the posterior lip, with cystic disease of its mucous membrane, and the whole everted portion covered with granulations that bleed easily when touched with the sound, and secrete a glairy fluid that soon becomes yellow.

Now what is the pathology here, and what are the causes that have led to this unfortunate condition?

The beginning of her troubles dates, as she tells us, from the birth of her sixth child, since which time she has steadily grown worse.

From the history of the case, and from what we now find, there doubtless followed her confinement a failure of that complete metamorphosis of the tissues of the puerperal uterus which we know as involution. In other words, this great mass of uterine tissue which should have undergone fatty degeneration and become absorbed and carried away by the bloodvessels and lymphatics, has only partially undergone this change; this wonderful transformation has been in some way checked before its full completion, and the uterus is left much larger and heavier than it should be, and has now passed into a chronic state of subinvolution. The causes that lead to this state are both general and local.

Among the general causes, and it is probably the principal cause in this case, is the rapid bearing of children by a woman who does not possess a great amount of physical strength, and whose health has been somewhat broken down thereby. The recuperative powers are not equal to the task, and all the processes of the body move slowly. It only needs some untoward circumstance to make involution following confinement or abortion impossible.

Indeed, debility from any cause would tend to favor subinvolution.

As to the local exciting causes of subinvolution I would say that anything that tends to keep up a congestion or irritation of the pelvic organs would act as such a cause. In this case we have a dislocation of the uterus backward, this condition interfering more or less with the circulation of the organ itself, as well as with the circulation of the adjacent tissues. Next we have obstinate constipation, which is frequently a marked exciting cause. As you know, the veins about the uterus are not supplied with valves, and you can easily understand how a descending colon and rectum, distended and overloaded with fecal matter, and pressing on the surrounding structures, would tend to keep up a passive congestion of the veins of the pelvis.

Doubtless, too, in chronic constipation the circulation through the liver is usually torpid, and the movement of the blood in the portal vein being retarded, the return circulation from the lower portion of the body is interfered with, and we thus have another cause added to the ones already mentioned, which tend to keep up the congestion of the pelvic tissues.

In the lacerated cervix we have a condition that, by reason of its continued irritation, causes a determination of blood to the part, and results, in a considerable proportion of cases, in causing enlargement and hyperæsthesia of the cervix, and may properly be classed under the head of local exciting causes of subinvolution.

One of the most common causes of the failure of

the uterus to return to its normal size after delivery, is that women get upon their feet too soon after confinement. If a woman is strong and vigorous, and there have been no accidents or complications attending or following her delivery, she may be able get upon her feet within a few days after the birth of her child, with no apparent bad result. But if she be delicate, as too many of our native-born Americans are, with their overwrought nervous systems, impaired digestions, and feeble muscles, the erect position, if assumed by the patient too soon after delivery, while the uterus is still large and heavy, and the vagina, the uterine ligaments, and all the pelvic tissues are relaxed, there is danger of displacement of the uterus, local congestions and inflammations due to exposure to cold, and, as a consequence, an interference with the return of the uterus to its original size.

If it is possible to do so, I know of no better investment of time and money than for a woman who is raising a family, to devote at least a month following her delivery to rest and quiet, and as free from excitement of any kind as may be. Unless she is confined to her bed by poor health, it is the only opportunity the mother of a family has to remain quiet long enough to get really rested, and I would advise you to inculcate, in the most thorough manner, the minds of your puerperal patients with the idea that a full month must be given up to rest and recuperation after delivery, and that a portion of each day after getting out of bed must be spent upon a lounge or couch for several weeks. Of so much consequence do I consider this advice, that I would again urge you to use all your eloquence to show your patients the advantages to be derived from a month's bodily and mental rest following confinement. How long the uterus has been retroverted, and what the cause, we are unable to determine.

It may have antedated the subinvolution, or even her first pregnancy, for the displacement does not necessarily cause sterility; but in this case, from the fact that she was well up to six years ago, it is probable that the displacement followed her confinement at that time, either as a consequence of getting up too soon, or of subinvolution, or of both.

The laceration of the cervix probably occurred at the same delivery, and was apparently caused by the rapid expulsion of the child through the cervix, and it remains unhealed to this day, owing to bad management during the first two weeks following confinement; viz., getting up too soon, and not keeping the parts clean by vaginal injections.

The probabilities are, that more or less laceration occurs in the larger proportion of all cases when the head or shoulders pass through the dilated cervix; and they are more likely to be extensive when cervical disease has previously existed, such as cystic disease of the mucous membrane, or cervical catarrh. These injuries however, unless very extensive, usually heal within the first ten days after delivery, and you can easily understand that such healing process is promoted by rest in bed, and the use of vaginal injections daily of warm water, to which have been added a few drops of carbolic acid.

When, owing to the extent of the injury, or the presence of untoward circumstances, the fissure does not heal, nor have—as in the case of the patient before you—a thickening of all the tissues of the cervix, an eversion of the mucous membrane that lines the cervical canal, and an erosion of more or less of the mucous membrane that covers the vaginal portion of the cervix; this erosion being produced by the profuse and irritating discharge from the everted cervical mucous membrane that is chafed and fretted against the walls of the vagina with each movement of the body.

The openings of some of the mucous follicles become closed by inflammation, and we have studded over the everted mucous membrane, small cysts the size of a split pea, containing a glairy fluid, which consists of the retained mucus. To the examining finger, they feel like shot beneath the mucous membrane, and are simply retention-cysts.

The prognosis here for the cure of the cystic disease, and of the laceration of the cervix is good; but the cure of the displacement of the uterus, and the enlargement of the body, is somewhat uncertain, and will depend principally upon our ability to return the uterus to its normal position, and to retain it there by some method that will not cause pain or irritation.

We will begin the treatment of this case by prescribing for her fl. ext. cascara sagrada, ℥j, fl. ext. nux vomica, and fl. ext. hyoscyamus, ää ℥j, of which mixture she will take a small teaspoonful every night at bedtime, until her bowels are regular.

We will order her to take fifteen drops of the fl. ext. ergot three times a day between her meals, for its effect upon the tissues of the uterus, and upon the bloodvessels of the pelvis. After the introduction of a Sims' speculum, the anterior lips of the cervix will be seized by a delicate vulsellum and steadied, and the cysts in the cervix freely punctured with a bistoury, and after the bleeding has stopped, we will paint the erosion and the site of the cysts with the comp. tinct. iodine.

The Simpson uterine sound will then be introduced into the uterus with the concavity backward, and slowly and gently rotated so as to bring its concavity forward, and thus place the uterus in a condition of anterversion. The post-cervical cul-de-sac will then be filled with pledgets of absorbent cotton like the one I show you, each with a strong thread attached for removal; and afterwards several larger pieces of cotton placed in the upper part of the vagina, in front of, and below the cervix. The object of the cotton tampon applied in this way, is to furnish a soft padding that will, in a measure, keep the tender uterus in its normal position for a time, enable the patient to stand upon her feet with more comfort, and to learn how the uterus will bear the pressure of an artificial support. This dressing will be removed in thirty-six hours; a large vaginal injection of hot water used night and morning, until she returns here in three days to have the uterus replaced and the dressing repeated.

As soon as the tenderness subsides, and the uterus is somewhat reduced in size under the influence of the hot water and the ergot, we will introduce a retroversion vaginal pessary to keep the uterus permanently in place. The laceration of the cervix will then be repaired, which will still further assist in reducing the size of the uterus; and if we can then induce her to go into the country for a few weeks or months, away from the cares and responsibilities of her family, we may expect permanent good results from our treatment.

ORIGINAL ARTICLES.

ON SOME COMPOUND ARTICULAR FRACTURES.

BY LEWIS A. STIMSON, M.D.,

PROFESSOR OF PHYSIOLOGY AND CLINICAL SURGERY IN THE UNIVERSITY OF THE CITY OF NEW YORK; ATTENDING SURGEON TO THE BELLEVUE AND PRESBYTERIAN HOSPITALS, NEW YORK.

(*Read before the New York Surgical Society, May 8, 1883.*)

THE surgery of the joints has already received, in the discussions of this Society, an attention to which the importance and variety of the lesions with which it deals, the permanent disabilities which these lesions so frequently cause, and the difficulties and embarrassments encountered in their

treatment fully entitle it. Among the more important traumatic lesions, compound fractures hold a prominent place. Equally with other injuries, they have shared in the benefits conferred by the recent great improvements in the treatment of wounds, and, so far as the severer forms are concerned, the rules of treatment have been drawn with sufficient distinctness. You will all, doubtless, remember cases that have been presented here in which formal primary excision of a joint that has been extensively mutilated in all its parts has not only saved the limb, but has also given the patient a new and useful joint. My wish is to ask your attention this evening, not to these extensive injuries, in which the question lies between excision and amputation, but to those lesser ones in which, the injury to the bone and soft parts being comparatively slight, the main feature is the implication of the joint, and the therapeutic problem is how best to avoid dangerous suppuration within it—cases in which the surgeon asks himself whether he is justified in striving for preservation of form and function, in seeking to convert the fracture into a simple one, in depending upon drainage and antiseptics to prevent suppuration, or whether he should not rather seek in partial or complete excision an inferior result, but one obtained with less risk to the patient.

The cases which I have now to relate are those of this class which have come under my care during the past year: they are three in number—one each of the elbow, knee, and ankle.

CASE I.—W. J. K., twenty-eight years old, fell to the ground, April 4, 1882, from the seat of a truck which he was driving, struck upon the palm of his right hand, and injured his elbow. He went at once to a small hospital, where, he says, the limb was handled for some time, causing him much pain, and he was then advised by the examiners to seek relief elsewhere. He came to the Presbyterian Hospital, where I saw him five hours after the accident, and recognized a dislocation backward at the elbow of both bones of the forearm. Ether was administered at his request, and the dislocation reduced easily. The skin was unbroken.

On further exploration, I found a movable, hard body, about half an inch long, lying under the skin on the outer side of the joint between the head of the radius and the olecranon, which, as the outlines of the olecranon, external condyle, and the accessible portion of the head of the radius were normal, I judged to be the inner portion of the head of the radius broken off when the bone was forced backward past the condyle. Believing that if left in place, or even if restored to its proper place, if that were possible, it would interfere very seriously with the subsequent mobility of the joint, I removed it at once by cutting straight down upon it. The joint was then washed out with a watery solution of carbolic acid, 1 in 40, a short drainage-tube inserted, the wound closed about it with two sutures, and a gauze dressing applied.

The fragment, which I now show, is a portion of the head of the radius, triangular in shape, comprising about one-third of the articular surface; it is 17 mm. long, 12 mm. wide, and 8 mm. thick, the latter measurement being in the direction of the longitudinal axis of the bone.

The patient's temperature, which reached 102° the first evening, sank steadily to 98½° on the morning of the eighth day. The dressing was not changed until the third day, when the tube was removed, and again on the eighth day, when the wound was found almost dry, and when I moved the joint through an arc of about 70°, rotated the wrist without causing pain, and reapplied the dressing. The patient left his bed shortly afterward, without permission, and walked about for two hours; in the evening, the joint became painful; the temperature rose to 100¾°, and the next morning to 103°, when I removed the dressing, and found no discharge; but the outer side of the joint was tender on pressure, red, and swollen. Reapplied dressing; posterior splint; ice-bag. Two days later (eleventh day), the wound discharged about two drachms of pus on pressure, and during the following week discharged freely on pressure over the outer side of the elbow. On the nineteenth day, I made a counter-opening on the outer side of the arm, about three inches above the wound, and, on the twenty-fourth day, opened a large subcutaneous abscess, on the inner side of the elbow, which communicated with the other, apparently by a track passing around posteriorly above the elbow. The flow of pus then diminished rapidly, and the openings closed within a month.

As the joint was only slightly movable, I forced it, under ether, on June 8, getting motion through a range of about 60°. When I last saw the patient, a week or two later, the greater part of this gain had been lost; the joint was free from pain, and the patient resumed work as a driver, promising to report from time to time. I have heard nothing from him since.

[*May 23.*—I met this man to-day. Flexion and extension at the elbow are almost complete; but rotation of the forearm is entirely lost. The arm is strong and serviceable.]

CASE II.—Edward C., twenty-two years old, was admitted to the Presbyterian Hospital, February 4, 1883, with a compound fracture of the left patella, caused the same day by a fall from a pillar of the elevated railway, which he was attempting to climb while intoxicated. The bone was broken transversely a little below its centre, without comminution and the fracture communicated largely with a clean-cut, transverse wound one and one-quarter inch long, lying directly in front of it; the edges of the wound and the surrounding parts showed no signs of having been bruised. The trousers showed a corresponding transverse cut at the knee. There was also a fracture of the left inferior maxilla, and a long vertical wound of the left cheek. The knee was dressed with carbolized gauze, and the limb placed on a single inclined plane.

The next day, when I first saw the case, I found the wound and the interval between the fragments occupied by a clot; removed it, enlarged the wound for half an inch on the inner side, washed out the joint thoroughly with a 1–20 carbolic solu-

tion, passed a drainage-tube into the joint on each side through an opening made at about the centre of the lateral aspect, brought the fragments together with a silver-wire suture, the loop of which included all the soft parts except the skin in front, but not the articular cartilage, brought the ends out through the incision, closed the wound with sutures, and applied a gauze dressing covered with cotton, bound on firmly. Posterior straight splint.

The dressing was changed the next day, because of pain, and not again until three days later, when pus was found to have formed under the skin on the outer side, rendering necessary a counter-opening three inches above the one made for the drainage-tube on that side. The patient's general condition was satisfactory; temperature 99¼°.

Three days later (February 12th) the drainage-tube was removed, and a fresh one inserted on the inner side under the skin alone, to drain a small cavity which had formed around and above the first tube. During the following week the dressing was changed every second or third day, and the patient seemed to be doing well, but his temperature rose every afternoon to 101°, and on the 21st of February he complained of pain on pressure in the lower third of the thigh, which was swollen and rather tense. There was apparently no liquid in the joint, and the openings yielded only a small amount of thick, creamy pus on pressure.

February 24.—I opened a large collection of pus which lay on the outer side of the lower portion of the thigh under the vastus externus, and which communicated imperfectly with the opening made for the drainage-tube on that side, and also with the outer angle of the wound. The incision made on this occasion was about six inches above the condyle; drainage-tube. After this the temperature sank to the normal level, the thigh shrunk to nearly its natural size, and the amount of pus diminished steadily.

March 12.—It is noted that the case had progressed satisfactorily during the preceding fortnight. The abscess on the outer side of the thigh had shrunk to the track of the tube, the last portion of which was removed that day; the pouch on the inner side had a capacity of about one ounce; the transverse wound in front of the patella was flat and partly cicatrized. The wire uniting the fragments was cut and removed on that day. The patella was movable laterally, and the knee could be flexed slightly without pain.

30th.—The dressing, which had been in place eleven days, was changed. All the openings, except the first two made for the drainage-tube, were closed, and the anterior wound had nearly cicatrized. The fragments of the patella were united, apparently, by a fibrous band about one-quarter of an inch long, and were movable upon each other.

The patient was discharged from the hospital April 2d, with instructions to wear a posterior splint, and report in a fortnight.

April 14.—Everything was found healed except the tube-opening on the outer side. Patient walks without crutch, and can flex the knee 10° without pain. Independent mobility of the fragments cannot be recognized.

On the 30th of April I removed a small fragment of the patella that was found under the skin, just above the opening of the drainage-tube on the outer side, and which had kept up suppuration at that point. The patella is freely movable laterally, and the mobility of the joint is increasing. [The patient was shown to the Society May 8.]

Case III.—Thomas S., forty-seven years old, was admitted to the Presbyterian Hospital, February 17, 1883, with a compound fracture at the left ankle, caused by a fall while walking in the street half an hour before admission. Intoxicated.

The left fibula was broken at a point about three inches above the tip of its malleolus; the internal malleolus was broken off at its base, and this fracture communicated with a transverse wound of the skin, directly over it, through which blood was flowing quite freely. A small piece of bone which lay in the wound was removed. The surface of the limb was washed with the carbolic solution, but the wound was not injected. A gauze dressing was applied, with side splints outside.

The next day, the dressing, which was saturated with blood, was changed. The patient was very tremulous, with slight hallucinations. On the third day, the dressings were again changed; the position of the foot corrected; a posterior and an external lateral splint of plaster of Paris applied next the skin, and a new dressing placed over all. This dressing remained in place until February 26, the tenth day, when the discharge came through. During the first seven days, the temperature did not rise above 99°; on the eighth day, it rose to 99½°, and on the tenth, to 100°. The alcoholic symptoms had disappeared by the end of the first week.

March 5.—The wound was found to be reduced to a small, flat sore, and a small cotton dressing was substituted for the gauze.

18th.—The wound was found entirely healed; a continuous plaster splint was applied from the toes to the knee, and the patient was discharged, March 24, at his own request.

May 7.—I learned that the joint was freely movable and painless; the patient had returned to work, and was troubled only by the swelling of the limb during the day.

While in the last case the course was entirely free from complications, and the result as satisfactory as after any simple fracture, and although in the other two the patients' lives were never in danger, and there was never even any anxiety concerning them, except such as is inseparable from a knowledge of the possibilities in such cases, yet in each recovery was delayed, the result marred, and the chance of the occurrence of dangerous complications notably increased by profuse and prolonged suppuration, and in each the course differed widely from the uneventful, uninterrupted, rapid progress to recovery seen in the third case, which is the ideal of treatment, and which many believe a rigorous use of the complete antiseptic method will ensure.

It would be manifestly improper to assume that

this difference in result was due solely to differences in the treatment of these cases; such a generalization from so limited a number of cases would be unwarranted; but a discussion of these differences may not be without value, and may bring out such details of experience and expressions of opinion by you as will enable us to formulate more closely rules of treatment to be applied in similar cases. The details of treatment and the differences were as follows:

In no case was the spray used; neither in the first nor in any subsequent dressing. At the first dressing, the wound was injected with the carbolic solution in the first two cases; in the third case, only the surface of the limb and wound were washed with the same solution. At no subsequent dressing was the wound, in either case, injected; at the most, a sponge saturated with the solution was squeezed over it. The dressing was the common carbolized gauze, applied dry in a single broad sheet of several thicknesses, or in several narrow strips, overlaping and crossing each other somewhat like those of a Scultetus bandage, for the sake of an easier and more accurate fit, bound on snugly with a roller bandage, and sometimes overlaid with a thick layer of cotton to equalize the pressure. The dressing was changed whenever the discharge came through, or whenever pain or a rise of temperature made inspection of the wound desirable. The drainage-tube in the first case was short, reaching probably down to the wound in the capsule, but not into the joint; it was removed on the third day. In the second case, fracture of patella, a drainage-tube was passed into the joint on each side, and left in place for a week. In the third, no tube was used.

In the second and third cases the joint was kept completely immobilized upon a splint for several weeks; in the first case it was immobilized for one week, and then, after the occurrence of suppuration, again until the cure was nearly complete.

There was no evidence of the putrefaction of the discharge in either case; and in the two that suppurated the drainage was efficient, and the pus came, not from the joint, but from cavities that formed in the cellular tissue beneath the skin and, in one, beneath the vastus externus. Why did these collections form? Why did suppuration occur at points so distant from the openings in the skin?

In the first case there appears to be a very definite, immediate, determining cause: the passive motion communicated on the eighth day, together with the use of the arm immediately afterward in dressing and moving about. Up to this time the patient had been doing very well; the swelling had subsided, and the wound was little more than a superficial sore. The swelling that followed the receipt of the injury was not greater than that commonly observed immediately after a dislocation of the elbow, and the passive motion was even much less than that which is frequently communicated in the treatment of the same injury. There must, therefore, have been a secondary, contributing cause; and that second cause I am disposed to find in the adjoining, partly healed track of the drainage-tube; the two acting upon the loose cellular tissue, modified in its nutrition and irritated by the previous swelling.

In the patella case, similar conditions existed; pus formed outside the joint and escaped alongside the drainage-tubes. The later abscess, which formed under the vastus externus, and required a separate opening, was a simple abscess by proximity or by direct continuation, such as is frequently seen.

The almost uninterrupted series of successes recently obtained in various arthrotomies done for the relief of deformity, especially in genu valgum, which are among the most brilliant triumphs of antiseptic surgery, shows that a compound articular fracture, produced by the surgeon with the minimum of violence and of injury to the surrounding soft parts, can be safely received and promptly repaired. In such cases, as also in those which have been here narrated, the joint is opened and a drainage-tube is commonly used. The differences, therefore, to which I think we must look for an explanation of the difference in the result, lie in the greater injury done in the latter to the soft parts, to the swelling, and to the occasional delay in beginning treatment—a delay for which thorough disinfection does not entirely compensate.

Again, if we compare the course of simple dislocation of the elbow with that of the first case, the principal difference is found in the addition in the latter of an incision, the presence of a drainage-tube for forty-eight hours, and the persistence for a few days of the unhealed track of that tube; and this difference was sufficient, with the aid of the slight irritation of motion, to provoke suppuration in the swollen tissues. The inference to be drawn is, I think, that the unbroken skin furnishes a protection for injured or irritated tissues for which antiseptic dressings and treatment are an uncertain substitute, and that we should be cautious in inferring that we can safely deal with such tissues in accordance with experience obtained in operations upon those that are uninjured and unirritated. There is reason to think that if this elbow had been kept at rest for a few days longer suppuration would not have taken place; but still, would it not have been better to postpone the operation itself, to have removed the displaced fragments of the head of the radius only after the subsidence of the irritation caused by the dislocation?

Of these three cases, the one that did best was the one that was least interfered with (it was also the one in which the injury was least, but the difference in this respect was not great enough, I think, to account for the difference in the results), and I find in this fact, and in the fundamental success obtained in all, ground for the belief that confidence in modern methods of treating wounds should incline the surgeon rather toward absolute conservatism than towards operative interference; that in cleanliness, drainage, and rest we have agents efficient in themselves to avert inflammation of the joint, or, failing that, to keep the inflammation within such limits that the risks of an operation, if it should become necessary, are not materially increased; that the safeguards now possessed against

the occurrence of formidable complications of wounds should give confidence to expect the comfortable healing of wounds accidentally inflicted, rather than stimulate to the voluntary creation of new ones; and that the broad rule of treatment in cases such as those under consideration should be to avoid excision, except when it is clearly indicated by the extent of the injury, the difficulty of establishing drainage, or by an economical reason arising from the function of the joint involved, and the social condition of the patient that may make mobility, even if combined with some insecurity, preferable to anchylosis.

CASE OF IMPETIGO HERPETIFORMIS: RECOVERY.

BY LOUIS A. DUHRING, M.D.,

PROFESSOR OF SKIN DISEASES IN THE UNIVERSITY OF PENNSYLVANIA.

IMPETIGO herpetiformis, first described and so named by Hebra, is a rare disease of the skin, about which but little has been written either abroad or in this country. As I have stated in the third edition of my treatise on skin diseases, it may manifest itself in a variety of forms, all having, however, certain features in common. Cases showing the several varieties of the disease have, from time to time, presented themselves to me, one of which I shall briefly describe with the following case:

Mrs. Noami P., aged 24, applied for advice at the University Hospital, December 26, 1882, suffering with a mixed vesicular, bullous, and pustular disease of the skin, occupying the greater portion of the general surface. The following history was obtained: She had enjoyed good health until seven months ago, when the disease of the skin made its appearance. At the time, she was six months pregnant, and in average health. The eruption began upon the abdomen, but within a week, the whole surface, including the hands and feet and fingers and toes, was invaded. The first lesions were wheals, which in a few days passed into vesicles and small blebs, accompanied with violent itching. The urticarial lesions soon ceased, vesicles, blebs, and pustules now appearing from day to day. The blebs possessed the peculiarity of refilling upon being opened. Many of the lesions came out as "water-blisters," and later became whitish pustules. This change was often noticeable when they refilled a second or a third time after being evacuated. The disease increased steadily in severe be flexe within a week of confinement. At times

30th.—The dre including even the mucous meme eleven days, was cha d vagina, was literally covered cept the first two made e their appearance in the closed, and the anterior weeks, at one time vesitrized. The fragments of ng, at another time vesiapparently, by a fibrous ba re of all three lesions. an inch long, and were mov pin-head to a pea, or

The patient was discharg different shapes, being April 2d, with instructions to ne. Some were flat, and report in a fortnight. being generally flat.

April 14.—Everything was fortnight. The dis the tube-opening on the outer almost unendurable. without crutch, and can flex us used afforded any relief, and anodynes were resorted to nightly. Early in the course of the disease, the nails of the fingers and toes became affected, and the hair fell out to a considerable extent. The child was born healthy at full term, four months ago. After delivery, the eruption began to decrease somewhat in severity, but it has nevertheless persisted, and now presents the same general characters as at first. In fact, at no time has the type of the eruption materially changed.

The following notes were recorded at the time of the examination: The patient is a blonde. She is tall and spare, and is evidently in poor general health; the expression is anxious, and she is both nervous and despondent, fearing that she will never recover. She has lost weight of late. The whole surface, especially the trunk and upper extremities, is the seat of a profuse multiform eruption, characterized by vesicles, vesico-pustules, pustules, and blebs, of the most varied sizes and shapes. Many of the vesicles are extremely small—pin-point, and pin-head sized. All are tense, and have a glistening, glazed look. The small lesions are, as a rule, flat and but little raised. The pustules are more variable in size, some being as large as peas, or even cherries; the blebs are in some instances as large as cherries, or even walnuts. None of the lesions show any disposition to rupture, and are in this respect distinctly herpetic. As a rule, they are not accompanied by redness of the skin, nor by marked areolæ; often they rise from apparently sound skin. Many of the larger ones have an irregular, jagged, or stellate outline, which gives them a "puckered" appearance, similar to that we sometimes see in herpes zoster. This peculiarity is particularly noticeable with the pustules. Vesicles, pustules, and blebs exist in all stages of evolution; vesicles are observed passing into pustules and also into blebs. Here and there vesicles and pustules are developed side by side, and owing to the fact that the latter are whitish rather than yellowish, the contrast is marked.

Another peculiarity to be mentioned is the tendency all the lesions evince to group—to occur in more or less well-defined clusters. At the same time, it must be stated that this does not exist in so marked a manner as in herpes zoster. For example, here and there two or three pustules are grouped, but oftener a number of vesicles are irregularly clustered, forming a patch the size of a dime or a quarter dollar. The eruption in no instance follows the course of nerve-tracts. The extensor surfaces are more affected than the flexor. The fingernails show two distinct transverse ridges, indicating attacks of cutaneous outbreak.

The patient was placed upon full doses of arsenical solution and wine of iron, and used locally an ointment of oleate of bismuth. The following week, new lesions still appearing, one-half of the general surface was anointed three times daily with precipitated sulphur, two drachms; olive oil, two drachms; lard, one ounce. Upon the other half of the body, the "liquor carbonis detergens" (an alcoholic solution of coal-tar), one part to four of water, was applied freely. Under these local reme-

dies, improvement set in at once, both seeming to act beneficially. The tarry preparation was subsequently used (full strength) upon the whole surface. A tonic saline aperient was also prescribed for daily use in connection with the iron and arsenical mixture, and under these remedies, the patient made a very satisfactory recovery. Six weeks ago she regarded herself as cured, and a few weeks later passed from under observation.

MEDICAL PROGRESS.

Drainage of the Non-puerperal Uterus.—E. Schwartz, of Halle, recommends drainage of the uterus in morbid states not directly due to the influence of parturition. Though the cavity of the non-puerperal uterus is smaller than the bladder and other cavities, which in their morbid states are constantly treated by drainage, yet the swelling of the mucous membrane, and the uterine flexions and deviations often obstruct the outward flow of secretions. Schwartz at first used rubber drainage-tubes, but found that these were liable either to be occluded, or else to produce slight hemorrhage. He then employed the sounds of Schede and Rümmel, which consist of a kind of trellis-work of very fine filaments of glass. If too large, they produce uterine colic. At first, the sounds produced an increased secretion, but in a few weeks it ceased altogether, and the patients were cured. He had had no disagreeable complications. The sounds are about two and one-half inches long, flexible, with a kind of handle at the upper extremity, to which a silk thread is attached in order to keep them more easily in the uterus; to the lower end another thread is attached, in case the patient may wish to remove them. The sounds are introduced by means of an ordinary hysterotome, after having been previously dipped in iodoform. In cases of endometritis they should be kept in the uterus for some months, being changed every three or four weeks. In amenorrhœa a few days is a sufficient time to keep them in position. In cases of mechanical dysmenorrhœa, Schwartz has had good results after a month's treatment.—*Centralbl. für Gynäk.*, March 31, 1883.

Condensed Milk as a Food.—The Commission of the French Society of Hygiene have published the following conclusions regarding condensed milk: 1. Condensed milk containing sugar, diluted with twice or four times its weight of water, may be considered as an article of food, and in some cases would prove useful. 2. Artificial milk thus prepared is incontestably inferior to good cow's milk. It is a healthy article of food, but only slightly nutritive. 3. The directions given in the prospectus are calculated to mislead the public. Condensed milk, diluted with from six to ten times its weight of water, cannot be classed as an article of food. 4. Newly born infants, which have been suckled for three or four months, may be weaned and fed with good cow's, goat's, or ass's milk, not mixed with water, and given in sufficient quantity. Condensed milk containing sugar, diluted with from two to three times its weight of water, may form part of the daily nourishment of such children; but it would be certainly imprudent to use it alone.—*British Medical Journal*, April 21, 1883.

Tarsotomy for Club-foot.—M. Bœckel, in a communication to the Société de Chirurgie of Paris, proposed tarsotomy as a treatment for congenital club-foot—especially equino-varus. This method of treatment, by removing the astragalus, he considers superior to all others, and shows that under the influence of a deformed astragalus, the foot gradually takes a vicious form. In forty published cases of the operation there were no accidents or complications. An immovable dressing is applied. Bœckel found that, in one of his patients, the limb was not shortened after the removal of the astragalus. M. Després thought that tenotomy should also be performed in connection with the tarsotomy, in order to get uniformly good results.—*Progrès Med.*, April 21, 1883.

Medicated Gelatine in Skin Diseases.—Dr. Pick regards medicated gelatine as a clean and convenient dressing in the local treatment of skin diseases, the use of plasters or bandages to retain the medication being entirely obviated. The patient applies the gelatine, previously melted in a water-bath, with a brush, and when dry, applies over it a thin coating of glycerine, which prevents the gelatine cracking or chipping off, and keeps it flexible. The gelatine is prepared as follows: Fifty parts of gelatine are dissolved in one hundred parts of distilled water, in a water-bath. The desired medicine is then added, the mixture being constantly stirred. Then set aside, and wrap in oiled paper when cool. The patient melts a portion of this cake in a saucer placed in hot water, and, when dissolved, applies it with a camel's-hair brush to the diseased surface. If a fresh application is desired, the patient takes a warm bath, which washes off the old dressing.—*Allgem. Wien. Med. Zeit.*, Feb. 13, 1883.

The Cause of Icterus Neonatorum.—Birch-Hirschfeld, relying on the evidence shown by the examination of six hundred bodies of infants, attributes a hepatic origin to the icterus so often found at that age. The immediate cause seems to be an œdema about the branches of the portal vein in the capsule of Glisson, which compresses the excretory bile-ducts. This theory is supported by the fact noted by Hofmeister, that one generally finds bile acids in the serous fluid contained in the pericardium of new-born children dead of icterus. As to malignant icterus neonatorum, Birch-Hirschfeld thinks, contrary to the opinion of his predecessors, more particularly of Renege, that the infection is conveyed, not through the umbilical artery, but through the vein.—*Le Progrès Med.*, April 21, 1883.

Alcoholic Purpura.—Vogelin says (*Th. de Paris*, 1882):

1. Alcoholism alone will suffice as an exciting cause of purpura in predisposed individuals.

2. Pathologically considered, this form of purpura is due to changes brought about by alcohol in the blood, in the walls of the capillaries, and in the vaso-motor system.

The precise manner, however, in which alcohol acts upon these elements has yet to be explained.

3. Alcoholic purpura runs a rapid course. While usually terminating favorably, it leaves a tendency to relapse.

4. Treatment should be directed, in general, to the functional troubles resulting from alcoholism, and specially to the conditions which underlie the petechial eruption. The measures adapted to ordinary purpura are also those best indicated in these cases.—*Journal of Cutaneous and Venereal Diseases*, June, 1883.

Quinine Carbimide in Erysipelas.—Turbin has treated five cases of erysipelas with the bimuriate of quinine carbimide. An aqueous solution of 60 to 65 per cent. was used, the amount being ℥x. One or two injections were sufficient. The erysipelatous parts were

then dressed with camphorated carbolized oil. Turbin has had no unpleasant symptoms from this treatment, though 71 local abscesses have been reported as occurring in 281 patients in whom 773 injections were made. It seems that this double salt has no advantage over other preparations of quinine.—*Revue des Sciences Médicales*, April, 1883.

ANÆSTHETICS DURING LABOR.—DR. THOMAS D. SAVILL, at the close of a paper on this subject, thus summarizes the main precautions, the observance of which would render the use of chloroform justifiable:

1. There are certain women who have a tendency to flood at every confinement, and others in whom there seems an already too great relaxation of fibre—weak, anæmic females in their eighth or tenth confinement; and to these it would be unadvisable to give chloroform, except for necessity. Happily, it is not these women who suffer the most pain, but rather those strong, healthy primiparæ whose pelves and general build approximate to the masculine type.

2. We should not give it when labor is complicated with severe vomiting, or with acute disease of the heart or lung, unless there be imperative call for it.

3. It should not be given to the full extent, except for operation, convulsions, or spasm of the cervix; and then it is most necessary that one person should devote his entire attention to it.

4. The inhalation should be stopped directly we find the pulse becoming very weak, or the respiration irregular.

5. Anything which makes us suspect a fatty or enfeebled cardiac wall should make us cautious in the use of chloroform. Here, as in cases other than those of labor, it is not the most extensive valvular disease (so long as it be attended by compensating hypertrophy), but the atrophied or degenerate wall that constitutes the source of danger. Unfortunately, the signs of these conditions are subtle and uncertain; but a fatty heart may be suspected by an exceedingly feeble cardiac impulse, combined with an almost inaudible first sound; or attacks of dyspnœa, vertigo, and syncope, in the absence of anæmia, or valvular lesion; or the copious deposit of fat in other parts of the body, and the occurrence of dropsy without adequate cause. A dilated heart may be suspected by increased area of præcordial dulness, combined with epigastric and venous pulsation, and a want of correspondence between the violence of the cardiac impulse and the strength of the pulse. Pericardial adhesions also form a great source of danger. They may be suspected when the heart's apex is fixed above its normal position, and does not shift with respiration: or when there is depression instead of protrusion of intercostal spaces over the position of the apex, giving a wavy character to the cardiac impulse.

6. The sixth and last precaution I would mention is this. In all cases we should take extra care to prevent the occurrence of hemorrhage after birth: by giving a full dose of ergot in a little warm water when the head reaches the perineum; by ceasing the chloroform immediately it is born; and by rousing the patient from her lethargy as soon as possible.—*British Medical Journal*, May 12, 1883.

INHALATIONS OF EUCALYPTOL IN INFECTIOUS DISEASES.—DENIAU highly recommends this treatment of infectious, and also of some non-infectious diseases, as croup, bronchitis, etc. The use of the atomized vapor has given very satisfactory results. The results of this treatment in diphtheria especially were unusually good. The patients were kept in a moist atmosphere of the eucalyptus vapor. All the cases of diphtheria treated in this manner at New Plymouth, Australia, recovered without grave symptoms. The false membranes were easily coughed up, and in some cases casts of the bronchi. Eucalyptus is also recommended as a useful inhalant in bronchitis, croup, and asthma, and is a favorite Australian remedy for influenza. It seems, too, that it would give good results in typhoid fever.—*Bull. Gén. de Thérap.*, April 30, 1883.

ALOPECIA PRÆMATURA.—DR. LASSAR recommends the following treatment for premature baldness: Wash the scalp thoroughly for fifteen minutes every day with tar-soap, or soft glycerine soap, or soap which contains iodide of sodium. This must be followed by a warm douche, gradually cooled, and finally with water containing corrosive sublimate, two parts per thousand. The hair is then dried, and a spirituous solution of naphthaline (one-half per cent.) is rubbed into the hair. Carbolic or salicylic acid (one and one-half to two and one-half per cent.) may also be employed in the douche. This treatment must be persisted in even for eight weeks or more. It is much more efficacious in the early stages.—*Berliner klin. Wochensch.*, April 16, 1883.

RESORCIN IN PURULENT VAGINITIS.—CHÉRON has used resorcin successfully in cases of purulent vaginitis, both in the acute and chronic stages. When specular examination is painful, he introduces a rubber tube into the vagina and injects, three times a day, the following solution (irrigating the vagina with it for about six to ten minutes): Resorcin ℥ijss, Water Oij. By the use of this solution the purulence rapidly diminishes, as does the pain on examination, and then the following may be employed: Resorcin ℥jss to ℥iij, Glycerole of starch f℥ij. This is introduced into the vagina through the speculum, by means of a tampon, and left in place for twelve or fifteen hours. This is done every other day. A cure is obtained much more rapidly by this means than with emollients and glycerite of tannin.—*Le Progrès Med.*, May 12, 1883.

CHRONIC MILIARY SUDAMINA.—PINARD, in *Le Courrier Méd.*, September 23, 1882, concludes an article on this subject as follows:

1. There exists as a sequel of acute sudamina (whether sporadic or epidemic), a hitherto undescribed form of the disease, for which I suggest the name *chronic miliary sudamina.*

2. In the majority of cases it follows in the course of a protracted convalescence from the acute form of the malady. Sometimes, however, in a district infected by acute sudamina, it occurs spontaneously and primarily, or after a short subacute stage.

3. According to my observations, it affects grown-up persons exclusively, and females are rather more liable to its attack than males.

4. Its leading symptoms resemble those of cerebro-spinal irritation, as described by Jaccoud. They are habitual and profuse sweats; a discrete and scanty miliary eruption; marked muscular paresis; persistent weakness of the stomach, followed by subjective sensations of heat and cold; neuralgic or rheumatic seizures; severe epigastric pains, and palpitation of the heart.

5. The complaint seldom varies in its manifestations, and lasts from a few months to three or four years, with a tendency to spontaneous cure.

6. Sulphate of quinine will be required in a few cases of chronic miliary sudamina, but, as a general rule, cold water and the continuous galvanic current are the only reliable remedies.—*Journ. of Cutan. and Venereal Diseases*, June, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, JUNE 2, 1883.

THE AMERICAN MEDICAL ASSOCIATION.

WE are not of those who decry the American Medical Association, either in its scientific, ethical, or social objects, and we hail the occasion of the annual meeting as one of great importance to the American medical profession. We presume no one will deny that the Association, since its organization, has been of service in diffusing a knowledge of rational medicine, elevating the tone of its members, and in promoting an acquaintance and friendship between men widely scattered, and unlikely to be brought together, except through its meetings. Whether all of these results have been accomplished in the highest degree desirable or possible is a question which we do not think it profitable at present to discuss.

More to the point is it to consider what the Association should seek to accomplish in the near future. In searching for an answer to such a question, there occur to us the following objects, the importance of which would appear to be somewhat in the order in which we shall place them.

First, the development and dissemination of accurate knowledge of rational and scientific medicine and such collateral sciences as lead to the former. To this end, it is important that the ablest men in the profession should be enlisted in the cause of the Association. This is not now fully the case, for although it has always had enrolled upon its list of members many of the strongest men, yet there are others who have been conspicuous by their absence. It is true that it is a pecuniary sacrifice to busy men to devote a week to attending the meeting of the Association, but, as a rule, it is they who can best afford the sacrifice, and we suggest that such a sacrifice, if it be not rewarded in the consciousness of pleasure to others less fortunate, may even be as bread cast upon the waters—to return after many days.

The Association, on the other hand, has also a part to play in attaining this most desirable object—the interest of the eminent men of the profession—and that is to ignore all partisan, geographical, or special reasons of any kind, in the appointments to positions involving the presumption of peculiar qualifications, but to select only those whose reputations acknowledgedly adapt them for the post to be filled, and especially not to appoint those who seek appointment for personal reasons. A by-law of the Association has frequently harassed the Committee on Nominations by preventing the election of desirable officers for the next year on account of their absence from the meeting of this year. The best interests of the Association would be promoted by the repeal of this law, as now proposed.

In the further development of the scientific aims of the Association, the method of work by sections is certainly that in which the best results have been accomplished by the British Medical Association, with the objects of which our own may be said to be identical. At the same time it must be admitted there is some reason for disappointment at the results of the work of the sections. We cannot but think that the formation of the various national societies devoted to the interests of the specialties, such as the American Surgical, Gynæcological, Ophthalmological, Laryngological, and others is almost wholly responsible for this. They have unquestionably taken away from the sections of the American Medical Association many men whose coöperation would have been most creditable. And believing as we do, that the same results could have been accomplished in the sections of the General Association, we confess that we regret the formation of these special societies—at least to the extent to which it has gone. There are no British Dermatological, Laryngological, or other special societies, and, therefore, the sections of that Association devoted to corresponding specialties have been brilliant successes. In taking this position, we do not, of course, wish to be considered as discouraging local societies devoted to the specialties. It would be a great waste of time for men interested in different specialties to sit in one general medical society, and listen to disquisitions upon subjects in which they have no interest, while it is certain, too, that the specialties would never have reached their present stage, but for such local organizations. But each section of the National Medical Association should be a national society devoted to the interest

of one or more specialties, and thus would be accomplished the object of such a society. It is further, not unlikely that men who are members of these different national special societies are prevented from attending the National Medical Association by the fact that they cannot afford the time and expense demanded by attendance on both. And thus, in a second way, does the section suffer by reason of the existence of the national special society.

These societies, however, now exist, and it is not likely that any influence which can be brought to bear will soon effect their discontinuance. But we still believe that the sections can be redeemed from their unsatisfactory position. On another occasion we may discuss the methods by which this might be accomplished.

We regard the Association as the guardian of the ethics of the profession, and if there were no other motive for its existence than this one, we feel that its existence would be justified. It needs but little thought to convince one's self that, whatever may be our shortcomings, the relations of medical men to each other are characterized by a higher degree of courtesy and mutual consideration than those between members of other professions, and between business men. This we believe to be due to the influence of the Code of Ethics, which is the crystallization of every principle of honor and unselfishness, and which owes its existence to the American Medical Association. We fear there is reason to believe that the impression made by these principles is now less vivid than it has been, and no opportunity should be lost of calling attention to the golden rules laid down in the Code of Ethics.

There is a work, too, in which it occurs to us the Association might be of great service, not only to the profession, but also to the community at large, although we confess we are not prepared to immediately suggest a method by which to grapple with it. It is the growing evil of the worst kinds of quackery. Any one who reads our daily papers cannot fail to be struck with the space occupied by specious advertisements of absurd nostrums for the cure of this and that affection, while the country is flooded with circulars having the same object. It is well known that the formulæ for these nostrums are, as a rule, exceedingly simple, as witness Mrs. Joanna Stevens' "Remedy for the Stone," and the famous St. John Long's liniment for rheumatism. At the same time, the analyses of these supposed remedies requires the highest chemical skill and is costly.—We simply throw out the suggestion, could infectiousiation make a better use of the funds in EASES. as croup, than to furnish the means for such vapor has g of this treatm expose the trickery and by good. The nds of dollars are taken the eucalypt those who can least

Finally, the social objects of the Association are by no means to be ignored. There is great advantage to all of us in intermingling with our fellows. Isolation tends to narrowness and egotism, and one of the most wholesome lessons to be learned in our intercourse with others is that there are others besides ourselves, as good and better, attrition with whom is of mutual advantage, whether in debate or at the dinner table.

CAN TUBERCULOSIS BE PRODUCED BY THE INOCULATION OF INDIFFERENT SUBSTANCES?

THAT a correct answer to this question is essential to a solution of the problem of the infectiousness of tuberculosis, which is now engaging the attention of pathologists and clinicians throughout the world, is evident. For if indifferent substances, like cheese or dried blood or inspissated pus, are capable of producing true tuberculosis, the operation of the inoculated bacillus of Koch may be precisely the same—that is, it may act simply as an irritant.

We have always thought that the adherents of the doctrine of the infectiousness of tuberculosis ignored too completely the results of experiments which tend to show that tuberculosis can thus be induced. This attitude is based largely, if not altogether, upon the result of Cohnheim's experiments. It is well known that this experimenter, in conjunction with Fränkel, first made a series of inoculation-experiments, which he then thought established the fact that tuberculosis could be induced by the inoculation of different substances. But in a second series of experiments, the results were negative, and he, in consequence, retracted the views he first held. This is, of course, a strong point, but it is doubtful whether we are, in consequence, justified in immediately ignoring the results of other experimenters. The most which is justified is a demand that these experiments should be carefully repeated.

In this view we are not without support, even in the home of Koch. For at a recent meeting of the Berlin Medical Society, Dr. P. Guttmann declared that among those whose experiments went to show that tuberculosis could be produced by the inoculation of indifferent substances were men against whose reputation for reliability no objection dare be made. He had recently examined the existing literature upon the subject, and, with two exceptions, the original papers. The list of names which he presented as being worthy of the highest confidence, is a valuable one for reference, and we commend it to those who vehemently declare that no pathologist worthy of the name any longer claims that tuberculosis can be produced by the inoculation of non-tubercular substances. All of

these authors made inoculations with true tubercle, the inoculations with non-tubercular material being control-experiments. Among Englishmen are Sanderson (*Brit. Med. Journ.*, 1868), Wilson Fox (*ibid.*), and Foulis (*Glasgow Med. Journ.*, 1875). Among French writers are Papillon, Nicol, and Leveran (*Gaz. des Hôp.*, 1871); and among Germans are Lebert and Wyss (Virchow's *Archiv*, Bd. 40), Gerlach (*ibid.*, Bd. 51), Waldenburg (*Treatise on Tuberculosis, Phthisis, and Scrofulosis*, 1869). All of these observers claim to have produced tuberculosis in this way. Two papers, one by Empis (*Report of the International Medical Congress in Paris*, 1867), another by Robinson (*Philada. Med. Times*, 1881), he had not seen in the original. Whether the nodules produced by Empis were true tubercles he thinks is doubtful. In Robinson's experiments, with the inoculation of non-tubercular matter, one-half were negative and one-half positive.

During the discussion which followed, Friedlander, in reiterating an objection previously made, that these experiments were unreliable, said that all were open to two sources of error, viz., the possible admixture of tubercular with indifferent material, and spontaneously acquired tuberculosis, the result of the animal's surroundings; that experimenters had usually allowed their animals to live so long that tuberculosis might readily have developed independently of inoculation, while Koch has shown that the infection of tubercle operates very quickly.

To these objections Guttmann replied that the first source of error named by Friedlander is such an evident one that every experimenter who engaged in such work has excluded it. As to the acquired tuberculosis, the possibility of it cannot be denied; but control-experiments have been made in which sound animals, not experimented upon, were kept under the same conditions as those which had been inoculated. Both sets of animals were killed at the same time, and in those inoculated was found miliary tuberculosis; in the others, none. In other experiments, the animals were killed a comparatively short time after inoculation, and yet tuberculosis was found in the different organs.

It is such facts as these which, to an unprejudiced observer, stand in the way of the acceptance of the doctrine that tuberculosis is an infectious disease. And we hold with Guttmann that there is sufficient evidence in favor of their existence to demand a careful repetition of the experiments on which they are based before we dare believe that tuberculosis is infectious. We say this, not in a spirit of antagonism, but of conservatism, which demands a fair examination of both sides of a question before a decision is reached.

THE ABUSE OF ATHLETIC SPORTS.

As the season approaches which naturally invites to a larger participation in outdoor athletic sports, a few reflections from a medical standpoint on the abuse of such games may not be untimely.

There are two ways (independent of accidental injuries by bats, balls, etc.) in which athletic sports may be made to prove injurious. First, in the production of temporary conditions, such as syncopal and convulsive attacks due to over-exertion and exposure to the sun's rays on the part of those unaccustomed to these influences. Such accidents may occur in any kind of athletic sport involving the conditions named, but may be well illustrated by a case which came under our notice within a week:—

A young man twenty-five years old, very strong, but occupied at indoor work, joined in a game of base ball on a moderately warm day in May. He became very much interested, and instead of playing an hour as he intended, he played for at least four hours. He became overheated, went home and ate his dinner, during which he became excited in conversation, arose from the table, went to his room, and fell in a fit. When seen, he was unconscious, and had been so for at least three hours, having a convulsive seizure every now and then. An enema containing half an ounce of turpentine promptly restored him to consciousness, and the next day but one he was at his work. This young man was in typical health, and had never had a convulsion before in his life; this one was doubtless reflex, due to irritation of undigested food upon hyperæmic nerve-centres, and was clearly the indirect result of the over-exertion and exposure to the sun.

More frequent and less serious are syncopal attacks due to the same cause. Many of our readers who in their student days have gone from the preceptor's office into the hay-field for a turn at haymaking, have probably experienced the uncomfortable sensation of "giving out," and have perhaps had to bear the ridicule of companions for some time afterward.

Both of these accidents may occur in almost any game, even if it involve moderate exertion, provided a suitable subject offers. Rarer, of course, are the more serious results of heat-stroke, or thermic fever, although these are not impossible on extremely hot days, when games last a long time and involve a great deal of exertion.

But there is a consequence more serious and more permanent than the two first mentioned which occasionally results from athletic sports. This is what may be termed, for want of a better name, "heart-strain." This is only possible where the game demands continuous effort, as in rowing and running, and possibly also in swimming. It does not apply

to cricket, base ball, or other games in which violent exertion is more or less interrupted. We have spoken of this condition as heart-strain, although it probably has its origin in the lungs. It is well known that the effect of continuous muscular exertion is to interfere with the aëration of the blood, which becomes overcharged with carbonic acid. It is known, too, that blood overcharged with carbonic acid cannot circulate with facility through the capillaries, especially of the lungs, and accumulates in them, and in the pulmonary veins. The column of blood which is driven by each systole of the right ventricle is resisted by the already filled capillaries and veins, and a high degree of tension results in the pulmonary artery. The semilunar valves are strained, sometimes made insufficient, and possibly even lacerated in extreme cases. If there be simple temporary insufficiency, a repetition of the long-continued effort in another race may so increase it as to make it permanent. Hypertrophy and dilatation of the right ventricle and auricle and general surcharging of the venous system succeed to this condition. To this ensue degeneration of the muscular substance of the heart, and to the previous shortness of breath are added palpitation and irregular action with their distressing consequences.

These consequences are, of course, not confined to athletic sports, but may attend prolonged exertion of any kind, attended with pulmonary congestion. Similar is the effect of prolonged "running to catch a train," and especially is this harmful to one who has passed middle-life, in whom the tissues have already commenced to degenerate. Who has not experienced the cardiac pain incident to such overexertion, which must be due to a state of tension of the pulmonary semilunar valves?

Finally, the "irritable heart" of the military service, the clinical history of which was so thoroughly given by Prof. Da Costa in the *American Journal of the Medical Sciences*, 1871, is probably in some instances, the result of causes similar to those above discussed. In others it appears to have resulted from less violent exertion, operating upon a heart enfeebled by previous illness, as chronic diarrhœa, etc.

It is not impossible, also, that the extra tension to which the left heart is subjected in its efforts to overcome the resistance of forced muscular contractions may also result in strain upon its vessels, although the injuries which these have suffered have generally ensued upon more sudden and forced muscular effort than is commonly practised in athletic sports.

In conclusion, while it is a matter of congratulation that out-door life is becoming more popular with girls, through the medium of lawn-tennis and similar games, and although the exercise thus taken is not of so violent a nature as to produce in them the results above referred to, it is to be remembered that even this degree of muscular activity during menstruation, is often harmful in other ways; and physicians who have the care of families with growing girls, ought never to lose sight of this fact. A timely word upon the subject may save a girl from a life of suffering.

IN the case of Fox *vs.* Gordon, involving the question of the right of the husband to remove the dead bodies of his wife and two children from the cemetery lot of his mother-in-law, the Master to whom the case was referred has decided, that there is, at least, a right of custody, if not of property. He quotes the very sensible remarks of Hon. Samuel B. Ruggles, of New York, in a similar case, that "the dogma of English ecclesiastical law, that a child has no such claim, . . . is so utterly inconsistent with every enlightened perception of personal right, so inexpressively repulsive to every proper moral sense, that its adoption would be an eternal disgrace to American jurisprudence. The establishment of a right so sacred ought not to need any judicial precedent.

"The person having charge of a body cannot, however, be considered the owner of it in any sense whatever; he holds it only as a sacred trust for the benefit of all who may, from family or friendship, have an interest in it."

BY capillary electrolysis is meant the utilization of a capillary trocar as the electrolytic needle. Dr. Henrot, who proposes this method, uses it in those cases of goitre containing cysts, and permeated by large veins. Whilst through the canula the fluid is removed, the canula, as a needle transmitting the galvanic current, brings about also the closure of the great veins. Dr. Henrot gives a case with minute details, in which this mode of treatment was entirely successful. If such an expedient be contrasted with the measures heretofore available for the treatment of vascular cystic goitre, its superiority becomes at once apparent.

DR. LEVERT has recently published a memoir advocating the use of ethyl bromide as the most suitable anæsthetic for lessening the pangs of labor. Assuming the propriety of the practice of inducing anæsthesia in all cases of labor, he maintains the superiority of ethyl bromide for these reasons:

It diminishes or suppresses the pain. It has no injurious effect on the mother or child. Labor proceeds more rapidly, and instrumental interference is less often necessary. After delivery, there are no accidents which can be properly referred to the anæsthetic, and the convalescence is rapid and sure.

REVIEWS.

THE SUBJECTION OF HAMLET. AN ESSAY TOWARD AN EXPLANATION OF THE MOTIVES OF THOUGHT AND ACTION OF SHAKESPEARE'S PRINCE OF DENMARK. By WILLIAM LEIGHTON, Author of "Shakespeare's Dream," etc. WITH AN INTRODUCTION BY JOSEPH CROSBY, Hon. M. R. S. L. Pp. 74. Philadelphia: J. B. Lippincott & Co., 1882.

THIS work may seem quite foreign to the review department of a medical journal. As, however, it deals with psychological questions, we may, so far as our space will allow, make some comments on the motive and character of the essay.

The mental condition of Hamlet has been a fruitful topic of discussion by philosophers, poets, and psychologists. Mr. Leighton enters into the discussion with a new theory. The contention has usually been between the view that the mental condition of Hamlet is feigned, and that which holds him to have been actually disordered in mind. Of course, it is the conception of Shakespeare, and not the actual Hamlet with which the question is concerned. Hence, what was the central idea of the great dramatist? Did he mean to convey the idea of a Prince at a Royal Court feigning madness to achieve his purpose of revenge? Or was his purpose to make the Prince actually melancholic, and suffer from acute exacerbations? Mr. Leighton maintains that it was Shakespeare's purpose to have it seem that the reason of the Prince was actually overthrown by the horrible events of which he became cognizant; by the superstitions connected with the appearance of the ghost, and the other supernatural adjuncts. This view is supported by ingenious reasoning; and although he makes no attempt to define the form of mental derangement, Mr. Leighton constructs a fine argument to prove mental unsoundness. The essay is well written and is an interesting exposition of his theory.

SOCIETY PROCEEDINGS.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Fifth Annual Congress, held in New York, May 21, 22, and 23, 1883.

(Specially reported for THE MEDICAL NEWS.)

(*Concluded from p. 610.*)

THIRD DAY. MAY 23D.—AFTERNOON SESSION.

DR. GEORGE W. MAJOR, of Montreal, read a paper on

THE VALUE OF POST-LARYNGEAL PAPILLOMATA AS A MEANS OF DIAGNOSIS IN TUBERCULAR DISEASE.

He held that although these growths were recognized as present in a number of cases of laryngeal phthisis, that no special importance as a means of diagnosis or prognosis has been attached to them. It was a difficult matter to say accurately in what proportion of cases of tubercle these developments were to be found, as frequently before coming under observation—laryngoscopically—the cases had either advanced to ulcerative changes, or undergone some local treatment modifying the condition of the facts. He thought about twenty per cent. of the cases might be a safe estimate. In his experience *feathery* papillomata occurring in the region stated were as valuable a means of diagnosing at a very early stage, and before physical signs had been developed, as any before the notice of the profession. Why this should be he did not pretend to say, any more than he would attempt to explain the proneness of other parts to first affection. The *velvety* growths he did not regard as of paramount value, but considered they should be carefully pronounced upon.

In his private practice, and in the Montreal General Hospital clinique, he had found the conditions referred to, to be a most valuable aid to diagnosis, when present, and had observed the rapidity with which tuberculosis extended in this class of cases.

His object, he said, in bringing the subject before the Fellows of the Association, was to elicit an expression of opinion from those whom opportunities so well fitted them to speak with authority.

DR. ASCH remarked that he had frequently observed in phthisical cases the inter-arytenoid projections described by Dr. Major, but that he had not considered them diagnostic of pulmonary disease as he had observed them in case of asthma, and in others in whom there was no tubercular complication; his treatment, in cases where the projections did not demand evulsion by the forceps, consisted in the application of astringents as described by Dr. Major.

DR. MAJOR said, in reply to Dr. Asch, that, in the "velvety" condition of the space under discussion, he had not found lung complication usually, but such cases were hereditarily tuberculous. After the filamentous stage, he had yet to see a case recover; he considered where that state had developed the prognosis was markedly unfavorable.

A CASE OF ENORMOUS TUMOR, REMOVED FROM THE GLOSSO-EPIGLOTTIC SINUS.

DR. F. C. MORGAN, of Washington, D. C., reported a case of a large pedunculated myxo-sarcoma, originating from the left glosso-epiglottic fossa and a portion of the lateral pharyngeal wall, in which he was enabled to remove the tumor in rather a novel and primitive manner, viz., by getting its pedicle between the tips of the *index* and *middle fingers*, and using considerable *torsion* and *force*.

The patient, a strong, well-devolped man, of forty-nine years, had long suffered from dyspnœa, dysphagia, and aphonia, which symptoms ceased almost immediately after the extraction. The tumor measured two and one-half inches in lesser, and two and three-quarter inches in greater circumference, was ovoid, of firm consistence, and had a pedicle one-quarter inch long.

Microscopic examination demonstrated that it was a myxo-sarcoma. The specimen and drawings were exhibited, and it was stated that the man is doing well, two and a half months after the operation. Laryngoscopic examination shows that the growth was completely removed.

During his remarks, Dr. Morgan took occasion to say that pharyngeal tumors are, according to his researches, not so rare as is generally claimed, and presented a tabular statement, embracing sixty-one authentic examples. Sarcomata predominate in the pharynx. In concluding, he submitted a complete bibliography of the entire subject, containing seventy references to interesting contributions.

DR. DEBLOIS said: In listening to the very instructive and interesting paper of Dr. Morgan, we may draw at least one useful suggestion from it, that is the proper use of our fingers. As our practice in laryngology becomes more and more scientific, so much the more are we addicted to the exclusive use of instruments to the exclusion of more natural means. And in this connection he would beg leave to suggest the propriety of the use of the finger-nail in the extirpation of growths in the larynx. He had the good fortune in this way to partially remove a growth from the vocal cord; where, owing to the hyperæsthesia of the parts, the introduction of the laryngeal forceps was impossi-

ble. Although this procedure may seem brutal, it appeared to him at least, quite as justifiable as in introducing the forceps at random when the parts cannot be seen.

With regard to the bibliography of the subject, he thought that the Association owed its thanks to Dr. Morgan, the extent of whose extensive and laborious researches had just been presented. There are few who would have sacrificed so much of their own time for our instruction.

DR. INGALS referred to a case of a very large growth in the naso-pharynx extending into the mouth, which greatly obstructed breathing, which was operated upon by Dr. Moses Gunn, of Chicago; who removed the tumor with his finger. He had not been able subsequently to discover the point of attachment of the tumor. With regard to the brutality of attempting to remove laryngeal growths with the finger, he would merely state that it would depend upon the size of the operator's finger.

DR. DELAVAN said that he recalled one of the cases referred to in the paper by Dr. Major; he had been present when the operation for its removal was performed by Dr. Wagner; it was in a girl of twenty-two years of age, who had not been aware of any difficulty in her throat until a few weeks before applying for treatment. Upon examination, a growth one and one-fourth inches long by three-fourths of an inch wide was seen depending upon the posterior border of the soft palate; it was found to be attached near the floor of the posterior nares on the left side. Schrötter's écraseur was used, but it was impossible to remove it in this way, and it was finally divided with great difficulty by means of a strong knife. Upon microscopic examination, the outer surface was found to be covered with a thick coating of epithelium having a horny layer, the basement membrane, and under this a thick layer of fat; in the centre of the tumor was a large double plate of true cartilage surrounded by a fibrous sheath of perichondrium; the point of interest in the case was that the patient had been unconscious of any difficulty in her throat until within a short time, although the growth was evidently congenital. It resembled the helix of a normal ear. He had at the time reported the case at a meeting of the New York Pathological Society, and had found that up to that time at least six cases had been placed on record. As to the removal of morbid growths in this locality with the finger, he thought the method particularly applicable in cases of adenoma at the vault of the pharynx; it seemed illogical to examine such a case with the finger and then resort for its removal to an instrument, when the examination and the removal might be combined in the one manipulation. He thought that the use of the finger-nail in certain favorable cases was even superior to the use of instruments.

DR. LINCOLN said that in order to illustrate the possibility of operating with the fingers through the mouth upon tumors of large size, he was prompted to add that in his researches upon the treatment of naso-pharyngeal tumors, in the paper which he had read yesterday, he found a report of a case of naso-pharyngeal polypus removed by Dr. Whitehead by the finger, unaided by instruments, if he remembered correctly.

DR. ASCH said that he would merely suggest that a difficulty is experienced in introducing the finger behind the palate in a great many cases, especially in women. There are, unquestionably, cases in which such a method could be applied, but in others it could not be carried out without severe laceration.

DR. BOSWORTH said that Meyer reports some three hundred cases of examination of the naso-pharynx with the fingers, and in which he relied upon the finger in diagnosis.

DR. MORRIS J. ASCH then read a paper entitled

A CASE OF SUDDEN DEATH OCCURRING AFTER TRACHEOTOMY, WITH REMARKS.

R. S., 44 years old, had been suffering for a year with hoarseness and difficulty in breathing, gradually increasing until at the time of presenting himself at the Throat Department of N. Y. Eye and Ear Infirmary, when he experienced attacks of suffocation on the slightest physical exertion; slight cough, although he did not complain of pulmonary disease. Examination showed complete paralysis of abductors of the larynx, with ulceration and infiltration of ventricular bands and ary-epiglottic folds. Tracheotomy was advised and performed, the patient doing well after the operation, the ordinary precautions having been observed, until the second day, when he suddenly expired during the visit of the attending surgeon to the ward. The death was attributed to heart-failure from fright; the post-mortem gave no material cause for the fatal result. The lesson to be learnt from this experience is that no case of tracheotomy performed for obstruction caused by acute or chronic disease, however, easy of performance, should be viewed as anything but a very serious affair, and that it is the wise part to be prepared for a sudden unfavorable result.

DR. ANDREW H. SMITH read a paper on

ADHESIONS OF THE VELUM TO THE WALLS OF THE PHARYNX,

usually the result of syphilis, and especially of late tertiary manifestations; when complete, is apt to cause deafness from otitis media, owing to confinement of secretions in pharynx in contact with the inner end of Eustachian tubes, and the absence of the influence of deglutition in keeping the middle ear inflated. Smell is lost, and taste impaired.

Treatment consists in dilating any opening which may exist, and keeping it open by daily passage of a sound by the patient. Complete adhesion requires a cutting operation, followed by the introduction of a tube, gutta-percha plate, or other device to keep the surfaces from readhering. Dr. Delavan had succeeded in one case in preventing adhesion by cauterizing with monochloractic acid, the eschar from which remains adherent until cicatrization is complete beneath.

DR. DEBLOIS said it was his good fortune last winter to have under his care a patient with adhesion of the velum in the posterior wall of the pharynx, such a condition as had been described by Dr. Smith. The nasal cavities were easily cleansed by filling them with Dobell's solution, and then, by forcing into one nostril a column of compressed air, the solution and the retained solutions were driven out through the other. Every day a small throat-mirror was forced up behind the uvula, and there is no doubt that an opening would have been made had it not been that there was a vertical perforation, the edges of which were so closely adherent that nothing could be forced between them; small bubbles of air only could be forced out behind the velum. Unfortunately, just as an operative procedure was determined upon, the patient was lost sight of. Dr. Delavan's suggestion for preventing these adhesions of the newly cut surfaces certainly appeared to him very valuable, and he hoped to be able to give it a trial.

DR. INGALS said that about two years ago, he had two little patients brought to him, the one seven the other nine years of age; in the younger one there was complete adhesion of the velum to the posterior wall, excepting a small opening about a line in length, in the older one a similar condition existed but the opening was a little larger. The mother stated that this condition had followed an attack of diphtheria. The

children had been under treatment by another physician for deafness; upon examination he found the naso-passages free. He inquired what could be done with such little patients, and whether an operation could be performed under an anæsthetic with perfect safety?

DR. SMITH said, in closing the discussion, that it appeared to him that the operation could be performed in these young subjects, but he doubted whether the advantages of an operation would be commensurate with its difficulties. He believed that it would be better to wait until the children had grown somewhat, and become more manageable. He did not see any especial difficulty in the administration of anæsthetics in these cases.

The PRESIDENT announced that the last scientific paper on the programme had been read, making in all twenty-one to which the Fellows had listened at the present Congress.

THE CHAIR appointed the retiring Vice-Presidents a Committee to conduct the newly elected President to his seat.

DR. LEFFERTS, on leaving the Chair, congratulated Dr. Bosworth upon his accession to the dignity and honors of the Presidential office, and also congratulated the Fellows of the Association upon their choice of a presiding officer for the coming year. In turning over to his successor the office, after a year's service, upon which he could look with feelings of honor and pride, he did so with wishes for the continued prosperity of the Association, which is now in the best condition in which it had ever been, and after one of the best meetings which it had ever held. He concluded with the cordial wish that the prosperity of the Association might continue during the coming year.

The PRESIDENT invited the Vice-Presidents to take their seats and introduced them to the Association. He said that he could only express his very cordial acknowledgment to the gentlemen of the Association for the very high honor they had conferred upon him in calling him to occupy this office during the coming year. He said that we belonged to a profession which offers very few rewards for work such as the world applauds, but he did not know that he could ever hope to receive a higher one than this. He felt that this Association was very largely indebted for its success to his predecessor, Dr. Lefferts, who had served them faithfully for five years as Secretary and Treasurer and in the Presidential office. The best wish that he could express for the Association, was that it might continue in as prosperous a condition as it was at present.

DR. INGALS, on behalf of the visiting Fellows, returned thanks for the warm hospitality the had received and their high appreciation of the retiring President's services. He expressed the sense of regret that the trouble of entertaining the Association should have been again put upon its members in New York City, but the visiting Fellows would help to make them as light as possible, and he promised a larger attendance from the west next year.

The PRESIDENT, DR. BOSWORTH, then announced the Fifth Annual Congress of the American Laryngological Association adjourned.

MEDICAL SOCIETY OF THE STATE OF NORTH CAROLINA.

Thirtieth Annual Meeting, held in Tarboro, May 15, 16, and 17, 1883.

(Specially reported for THE MEDICAL NEWS.)

FIRST DAY, MAY 15TH.—MORNING SESSION.

THE Society met in Annual Session on Tuesday, May 15, at 10 A. M., and was called to order by DR. L. L. STATON, *Chairman of the Committee of Arrangements.*

DONALD GILLIAM, ESQ., of the Tarboro bar, delivered an

ADDRESS OF WELCOME,

and the PRESIDENT, DR. J. K. HALL, of Greensboro, responded to the address, and accepted in behalf of the Society the hospitalities offered.

After the calling of the roll, the President appointed as a *Committee on Credentials*, DRS. PITTMAN, O'HAGAN, and WHITEHEAD; on *Finance*, DRS. JONES, MCDONALD, and SPEIGHT.

DR. O'HAGAN introduced DRS. CHAS. M. SHIELDS, and LEWIS WHEAT, *Delegates from the Virginia Medical Association.* They were invited to a seat on the floor, and to participate in the meeting.

AFTERNOON SESSION.

THE SECRETARY read, on behalf of DR. R. L. PAYNE, JR., *Chairman*, who was unable to be present, the

REPORT OF THE SECTION ON SURGERY.

DR. L. L. STATON, of Tarboro, reported a case of

ABDOMINAL ABSCESS.

DR. HAIGHT, of Wilmington, reported a similar case, in which the bowels were relieved by the use of belladonna. An incision seven inches long was made over the swelling, and a fecal odor was at once observed. A large amount of pus was evacuated, and the opening closed. A fistula subsequently formed.

The Report of the Treasurer showed a balance on hand of $71.80.

SECOND DAY, MAY 16TH.—MORNING SESSION.

The report of the *Committee on Obituaries* was made by Dr. Holms, Chairman.

DR. DUFFEY, of Newberne, reported a case of

ARTERIO-VENOUS ANEURISM.

Seven years ago the patient received an injury to the side of the head just behind the ear. Two years after this she complained of pain, and an irregular, tortuous, pulsating tumor about the sige of a turkey's egg had developed in the course of the posterior auricular artery. An operation was proposed, but the woman would not consent to it, and she was then lost sight of for some time. When the aneurism was again examined it was found much enlarged. Both the arteries and veins of the region were enlarged and tortuous. Behind the pinna of the ear and under the integument of its posterior surface was a large pulsating cavity. In front of the tragus was another cavity, not quite so large. This corresponded to the position of the temporal artery. Nearly the whole surface of the pinna was distended and pulsating. The external jugular vein was two to two and one-half inches in circumference.

The woman was informed that it was only a question of time when the tumor would burst, and was instructed to catch and hold the rent until surgical aid could be procured.

On July 2, 1882, the place pained her very much, and the next night the tumor burst. Her husband seized the rent and stopped the bleeding. Dr. Duffey saw her next morning and found that she had lost much blood. The common carotid was tied low down for fear of the upper portion being diseased. During the operation a vein was cut near the jugular and much hemorrhage occurred. This was checked by ligation. The aneurism was now freed from clot, pressure removed, and blood was seen to flow freely from the rent in the sac, although the artery was tied. This was

stopped by passing long pins beneath the sac and applying a figure-of-eight suture. Compresses and bandage were put over this and the woman placed in bed.

All went well for a few weeks, when hemorrhage occurred at another point where the wall was very thin. This was stopped as before by means of pins. The wound made in ligating the artery healed well, but after all this, bleeding occurred a third time. Small pieces of compressed sponge were now packed over the surface and around the tumor, and confined by bandage. Over this, and around the head and lower jaw, about five yards of garter elastic were applied, the band being drawn very tightly.

The centre of the tumor was left exposed, and into this thirty minims of persulphate of iron injected. The elastic was removed in about two hours on account of the unbearable pain it produced. The patient did well after this. A little sloughing took place at the point of injection, nothing more. The tumor soon began to shrink, and all that is now left of the old tumor is a small fluid portion which fluctuates, and will require another operation.

DR. SATCHWELL, of Rocky Point, read a paper on

ANTISEPTIC SURGERY.

DR. FURGERSON, of Halifax, presented *Three Morbid Specimens*.

DR. M. L. JAMES, of the Virginia Medical College, was introduced by Dr. Moore, and invited to participate in the deliberations.

A COMMITTEE ON NOMINATIONS

was appointed, consisting of Drs. Pittmann, Summerell, Foote, Farson and McDuffee.

A JOINT MEETING OF THE SOCIETY AND STATE BOARD OF HEALTH

was then held. There being two vacancies in the Board, DRS. J. W. JONES and D. MCDONALD were elected to fill them.

AFTERNOON SESSION.

DR. FOOTE, of Warrenton, reported a case of death from opium taken by mistake for quinine. Dr. Foote then offered a resolution which set forth that all poisonous drugs should be kept in bottles or packages of such shape as to be as easily recognized by the sense of touch as by sight.

DR. WOOD suggested that a committee be appointed to confer with the State Pharmaceutical Association, for the purpose of adopting such resolutions as may be thought best.

DR. FURGERSON, of Halifax, presented the report of the chairman of the

SECTION ON MATERIA MEDICA AND THERAPEUTICS.

DR. HILL, of Goldsboro, read a short paper on the

AMBROSIA TRIFIDA, OR RAG-WEED,

a plant indigenous to this State. He has used the plant as a styptic in epistaxis, pulmonary and uterine hemorrhage, hemorrhage from the bowels, hemorrhagic diathesis, etc., and found it of great value.

DR. SUMMERELL, of Salisbury, confirmed Dr. Hill's experience with the plant.

On motion of DR. MCDONALD, the plant was referred to Dr. Wood for classification and description.

DR. HOLMS, of Clinton, reported a

SUCCESSFUL REMOVAL OF A MULTILOCULAR OVARIAN TUMOR.

DR. MCDUFFEY, of Fayetville, read a paper on *Syphilis*.

At 8 P. M., DR. W. R. WILSON delivered the *Annual Address*.

THIRD DAY, MAY 17TH.—MORNING SESSION.

The reading of the annual essay was dispensed with on account of the illness of Dr. Barringer, its author.

MISCELLANEOUS BUSINESS.

DR. ROUNDTREE offered the resignations of DRS. HYOT and BRYANT, of Kingston.

DR. HINES, of Raleigh, offered a resolution which authorized the Secretary of the Board of Medical Examiners to publish for four weeks, in their respective county papers, the names of those doctors who had just passed an approved examination before the Board. The resolution was adopted.

DR. HINES thought this was only justice to the young men joining the Society, from the fact that there were many men in the State who were practising medicine, but who had attended but one course of medical lectures, and consequently had not joined the Society. This would give the people an opportunity of knowing who were the qualified physicians.

THE NOMINATING COMMITTEE

made the following report:

CHAIRMEN OF SECTIONS:

Surgery, DR. L. L. STATON, of Tarboro.
Practice, DR. W. P. MERCER, of Toisnot.
Microscopy and Pathology, DR. JOHN WHITEHEAD, of Salisbury.
Obstetrics and Gynæcology, DR. S. B. JONES, of Charlotte.
Materia Medica and Therapeutics, DR. J. T. STRICKLAND, of Thomasville.
Diseases of Children, DR. KEMP BATTLE, of Chapel Hill.
Orator, DR. JULIAN BAKER, of Tarboro.
Essayist, DR. J. L. NICHOLSON, of Onslow.

OFFICERS FOR THE ENSUING YEAR:

President.—DR. A. B. PEARCE, of Weldon.
First Vice-President.—DR. F. W. POTTER.
Second Vice-President.—DR. GEO. W. GRAHAM.
Third Vice-President.—DR. R. DILLARD.
Fourth Vice-President.—DR. GEO. W. LONG.
Treasurer.—DR. A. G. CARR, of Durham.
Secretary.—DR. L. J. PICOT, of Littleton.

DELEGATES TO AMERICAN MEDICAL ASSOCIATION:

DRS. JNO. MCDONALD, A. W. KNOX, H. R. HOOD, WM. CHEATHAM, J. W. MCNEAL, THOMAS HILL, S. S. LATCHWELL, T. S. BURBANKS, L. F. LEWIS, D. J. CAIN, and W. H. LILLY.

DR. GEORGE W. LONG, of Graham, read the *Report of Section on Practice of Medicine*.

THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE.

DR. WOOD, of Wilmington, offered a resolution requesting our representatives in Congress to use their efforts in procuring a fire-proof building for the library of the Surgeon-General's Office. The resolution was adopted, and a committee consisting of DRS. WOOD, HAIGH, and DUFFEY, appointed to confer with the representatives on this subject.

DR. CARR, of Durham, read the report on

DISEASES OF CHILDREN.

DR. MACON reported a case of *Opium Poisoning* successfully treated by atropia.

AFTERNOON SESSION.

The paper on *Obstetrics and Gynæcology*, by DR. HADLEY, and that on *Microscopy and Pathology*, by DR. CROWELL, in the absence of the authors, were referred to the Committee on Publication.

A vote of thanks was tendered the citizens of Tarboro, and the members of the Edgecomb County Medical

Society, for the hospitalities which they had shown to the State Medical Society.

The Society then adjourned to meet in Raleigh on the third Tuesday in May, 1884.

At 8 P.M. a handsome banquet was given by the Edgecomb County Medical Society.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, May 8, 1883.

THE PRESIDENT, T. M. MARKOE, M.D., IN THE CHAIR.

FRACTURE OF THE PATELLA.

DR. L. A. STIMSON presented a patient who had suffered from an ordinary transverse fracture of the patella. The result was very close union, but with recognizable mobility of the fragments upon each other. The treatment consisted in immobilization of the limb, with a fenestrated plaster apparatus, in the extended position; the fragments being held in contact with India-rubber tubing, one piece above and the other below the patella. The fracture occurred twelve weeks ago, and when first examined the fragments were separated from three-fourths of an inch to an inch. An interesting feature of the case was the fact that the patient had suffered from fracture of the patella on the opposite limb fifteen years ago, which was treated with an iron horseshoe arrangement, and apparently bony union had taken place.

Dr. Stimson presented a second patient with compound fracture of the patella, in whom the mobility of the joint was about the same as that in the first case, two weeks ago. The details of the history of the case appear in the following paper.

DR. STIMSON then read a paper

ON SOME COMPOUND ARTICULAR FRACTURES.

(See page 612.)

DR. POST said he remembered the time when compound fracture of the knee-joint was regarded as *ipso facto* calling for amputation. He recalled a case in the New York Hospital, and under the care of Dr. Kearney Rogers; a laboring man, who had his patella fractured by frozen earth falling upon the limb; and there was a free transverse wound opening into the knee-joint. The surgeons decided that the limb should be amputated, but the patient decided that the operation should not be performed. The external wound was very free, so that drainage readily took place, and the patient recovered without any considerable amount of inflammation. This occurred about the year 1840, and to the best of his recollection was the earliest case which opened the eyes of the surgeons to the expediency of attempting to save the limb in cases of knee-joint fractures.

DR. KEYES said he had just received a letter from one of his former students (Dr. Alexander), now in London, stating that he had recently followed Mr. Lister in the treatment of two cases of simple fracture of the olecranon by opening the joint, drawing the fragments together with wire, hammering the ends of the sutures down smoothly, and then closing the wound. The operations were performed under full antiseptic precautions, and all of the patients had done well; that is, neither suppuration nor inflammation had occurred. What the ultimate result would be, with reference to mobility, of course had not been ascertained.

Dr. Keyes had treated one case bearing on the subject in Bellevue Hospital; that of a boy, who had suppuration of the knee-joint with necrosis of the patella. The condition was due to a traumatic cause, the exact nature of which he did not recall, but the suppurative process invaded the joint. Dr. Keyes opened the joint freely upon both sides, passed a drainage-tube completely through the limb, and washed it out freely with an antiseptic solution. At about the same time suppuration occurred above the patella, and he opened the abscess and finally removed the entire patella. In the dressing, simple cleanliness was observed and complete drainage secured, and the boy recovered with a movable joint and a new patella.

DR. SANDS recalled a number of cases in which recovery had taken place after compound fracture of joints. He remembered one, a case of compound fracture of the patella, which he had treated in Bellevue Hospital. As in the case mentioned by Dr. Post, it was believed that the joint would suppurate, and it was thought that amputation was advisable, but under simple dressings the wound closed, suppuration did not occur, and the man recovered with a perfectly normal joint. He had seen a number of cases of fracture into the elbow-joint which had recovered, some with and some without antiseptic dressing. He had also excised the astragalus in two cases, one a compound dislocation with fracture, and the other a fracture in which the greater part of the bone was displaced, and pressed upon the soft parts, threatening mortification. In the last case, an opening was made, and the fragment of bone was removed. In the first case, no antiseptic dressing whatever was employed. In the second case, full antiseptic precautions were observed at first, but the physician, under whose charge the case remained, substituted a simple water-dressing, and the patient did well. In both cases, the patients recovered with a limited amount of motion at the ankle, as might be expected after such an injury.

Dr. Sands thought the point which Dr. Stimson made with regard to the concomitant injury of the soft parts in cases of fracture was a very important one. He believed that most surgeons would agree that often the least important lesion in cases of fracture is that of the bone, and that compound fractures often do badly because the soft parts are so severely injured that their vitality cannot be maintained.

Whether American surgeons were not thoroughly well versed in antiseptic methods, he was not prepared to say; but evidently the results obtained in this country were not so favorable as those which had been published in foreign journals.

Sometimes operation-wounds of joints pursue an unfavorable course in spite of every precaution; for example, in a case of old fracture of the patella, treated at one of our hospitals, by joining together the fragments with silver wire, the Listerian method was strictly carried out; nevertheless, suppuration followed, and the patient lost her life. In another instance, in which a simple fracture of the patella was converted into a compound fracture, and the bones were wired together, the patient had a severe attack of inflammation of the joint, and was very ill for a long time, although she finally recovered with a stiff joint. He should be disposed to treat a compound fracture of a joint by very careful washing with an antiseptic solution, by free drainage, and with the least amount of excision possible.

DR. GERSTER was able to recall a few cases of fracture involving joints, one of which perhaps was worthy of mention. A grocer, while unloading a heavy cask, lost his balance, fell, striking upon one elbow, and the barrel rolled over the same arm. Dr. Calle had charge of the case, and found an extensive compound fracture of the elbow-joint, both condyles being involved, and a single split of the bone entering the joint, so that the whole fracture presented an appearance very much like that of the letter Y. The external condyle was completely detached. On the outside of the limb there

was a large lacerated wound opening into the joint. The periosteum having been almost entirely torn from the external condyle, Dr. Gerster removed the bone, together with the eminence corresponding to the articulating surface of the radius. The spurlike sharp projection of the diaphysis of the humerus was sawn off, and a counter-opening was made on the inner aspect of the joint. The wound was washed out well with a five per cent. solution of carbolic acid. Drainage-tubes were inserted, and the wound in the soft parts was united by a sufficient number of sutures to give the joint a certain amount of support. Antiseptic dressings were applied, and the limb was placed upon a splint. When the patient came from under the influence of the ether, he went into a condition of violent mania, and thrashed about with the injured arm very severely. After he had been quieted by a hypodermic injection of morphine, the dressings were removed, and it was found that a large venous hemorrhage had taken place, which was controlled by pressure, and the dressings, with the splint, were reapplied. Despite the extensive injury originally done to the limb, and subsequently by the violence of the patient, the case did very well. No fever followed, and Dr. Gerster attributed the result largely to the fact that it came under observation very early, before any infectious process had commenced in the wound. The final result was that perfectly good motion was established. A small fistula remained open about five months, and then closed, and mobility subsequently became perfect. Passive motion was begun about the third week. There may have been some new bone-formation, but nothing like an external condyle developed. The radius was fixed in its normal position, and all of the motions of the limb were apparently complete.

Dr. Gerster related a second case, one of extensive injury of the ankle-joint. The injury was caused by falling from a wagon, breaking the ankle, and the patient was brought into the hospital five hours afterward, where the wound was dressed without washing, and simply by sealing it up. Within three days, intense phlegmonous inflammation developed, and amputation was necessitated in order to save the patient's life. Early and thorough-going aseptic measures must decide the fate of the injured limb.

DR. POORE referred to a case of compound fracture of the ankle-joint, which he saw when an interne in the Old New York Hospital. The end of the tibia protruded and was cut off. Suppuration of the joint occurred, but the man recovered with good motion.

DR. BRIDDON said that twenty-five years ago it was a disputed point as to whether it was proper or improper to resort to excision of protruding bones in compound fracture of the ankle-joint.

DR. POST said there was a case of malpractice on record, for cutting off the protruding extremity of the bone under these circumstances, and so far as he could recollect, the case was decided in favor of the surgeon.

THE PRESIDENT said that his own convictions were in favor of a certain plan of treatment well known to the Society, namely, that by through drainage, and by the use of it he had secured very satisfactory results. The drainage-tube is retained in the wound until granulation has fairly begun. He had employed it in compound fracture of the elbow-joint, but he did not remember to have used it in any case of similar injury to the knee-joint. In the elbow-joint he passed it through the capsule always behind the joint, and allowed it to remain from four to six days.

DR. STIMSON asked if in the third case which he reported, the President would have treated it by means of thorough drainage.

THE PRESIDENT answered that he would not, that he would have in that instance sealed the wound with collodion.

DR. BRIDDON presented specimens accompanied with the following history.

EXCISION OF TONGUE AND FLOOR OF MOUTH, LIGATION OF BOTH LINGUAL ARTERIES.

David, aged sixty-five, native of Ireland, single, laborer, family history good, is not aware of any predisposition to cancer, no history of syphilis, has been a smoker for thirty years. Three months ago he noticed something on the under surface of the tongue, that impeded its movement, especially preventing protrusion; it gradually increased, was not exceedingly painful but interfered with eating and talking; has had no hemorrhages, but complains of pain in his left ear.

Admitted to Presbyterian Hospital, April 27, 1883. Examination of mouth reveals an irregularly shaped ulcer involving the under surface of the tongue and the floor of the mouth as far forwards as the internal surface of the anterior portion of the lower jaw. It involves principally the left side of the tongue, but passing across the mesial line it encroaches on the right. Its edges are slightly everted, unequal, irregular, excavated, base indurated, motions of the organ impeded, he cannot elevate its tips, ganglions not involved, spontaneous lancinating pain, darting towards ear. Diagnosis, epithelioma; removal advised. Operation May 2, 1883, 2.30 P.M., under the influence of ether. The superficial veins were very large, the facial as it passed over the jaw equalling in size the little finger, and as the incisions had to be carried into close proximity with them, it was necessary to proceed with deliberation; on the right side the superficial structures were divided until the posterior belly of the digastric muscle and the hypoglossal nerve were exposed, the greater cornu of the hyoid bone was steadied with a uterine tenaculum, a curved needle carrying a ligature was then passed under and around it, and traction upon this brought the process nearer to the surface and steadied the hyoglossus muscle, an incision was then made through the muscle parallel with and below the nerve, and the artery was exposed without any further difficulty and was secured with a carbolized silk ligature.

On the left side the artery was tied within the digastric triangle. Considerable difficulty was experienced in separating the capsule of the submaxillary gland. It will be remembered that the disease was most extensive on this side of the mouth, and that might have had something to do with it; at all events the gland was suspiciously indurated, but not so much so as to warrant its removal. It was not an easy matter to keep it out of the field of operation. The artery was found below the nerve, but it was more difficult to isolate than on the right side; it was also secured with a silk ligature.

Attention was then paid to the mouth. A scalpel was then carried round the maxilla close to the bone, but not quite anterior to the limits of the disease. The soft parts were then cleared from the surface of the genio-hyoid muscles by strong, blunt-pointed curved scissors. This dissection was carried beyond the limits of the disease, and then a transverse section completed the extirpation; a few small bleeding points were secured in the floor of the mouth, and all the soft parts covering the posterior surface of the front of the jaw were removed with the sharp spoon. For three or four days there was considerable swelling below the left side of the jaw, but it has subsided; fetor of the mouth has diminished under the hourly use of a wash consisting of borax, glycerine, and tincture of

benzoin, and now six days after the operation he is sitting up in bed doing well.

DR. BRIDDON also presented fragments of bone removed from the elbow-joint.

FUNGOUS ARTHRITIS, RESECTION OF ELBOW-JOINT.

Maurice W., aged 40, native of Ireland, married, longshoreman, says that his family history is good, and that he has always regarded himself as a healthy man. He fell on his left elbow three years ago, but continued to work for two years, complaining only occasionally of soreness in the joint, eighteen months after the injury the joint began to grow stiff, and this condition increased until eight months ago, when pain became more annoying, and it became red and swollen, several incisions were made at that time evacuating matter, the incisions contracted, and the discharge continued in diminishing quantity.

Admitted to Presbyterian Hospital, April 23, 1883. General condition pretty good, left arm flexed to nearly a right angle, the elbow-joint is occupied by a fusiform swelling that reaches three inches above and four below the line of articulation; movements limited, but not accompanied by crepitus; above the superficial swelling there can be detected a deeper seated swelling, evidently periosteal, and reaching to the middle of the humerus; there are several puckered cicatrices about the joint, and the partially healed remains of an incision recently made; through several of these sinuses a probe appears to traverse the joint, and at one point comes in contact with carious bone.

Diagnosis, fungous arthritis; resection advised. Operation was performed May 5th under the influence of ether by the ordinary method of procedure. The joint was found completely disorganized, cartilages destroyed, nearly everywhere the dense lamella of bone that underlies the cartilage was gone, and the cancellous structure exposed, its spaces filled with granulation tissue.

DR. HALSTED suggested that the reason why Dr. Briddon experienced so much difficulty in securing the lingual artery upon one side, was that his assistant, while attempting to draw the hypoglossal nerve out of the way with a hook, at the same time raised the lingual artery with it, and the hyoglossus muscle. He thought this was the case, because, as soon as the assistant relaxed his hold with the hook, the artery was readily exposed. Dr. Halstead also offered the suggestion, that instead of dividing the muscle at right angles with the direction of the fibres, ligation would be facilitated considerably by simply separating the fasciculi to any extent which might be necessary without cutting.

DR. DRIDDON remarked that he was particularly struck with the facility given to the operation by fixing the greater cornu of the hyoid bone with a thread, so that it could be placed under the complete control of the assistant.

DR. POST believed it to be a general surgical principle, that wherever a loop of thread could be used instead of the forceps or hook to secure mere fixation, it was much more desirable than to employ the vulsellum or hook, or other means, as it was more secure.

DR. STIMSON said it seemed to him from the facility with which the tongue could be drawn out from the mouth—a fact mentioned by Dr. Briddon—that the hemorrhage might have been controlled very readily, even if it had been much more severe than it was.

DR. BRIDDON said his impression was that Whitehead's operation would do away with the necessity of ligating the lingual artery at all in these operations.

The PRESIDENT remarked, concerning the second specimen presented by Dr. Briddon, that about three weeks ago he excised the elbow-joint for caries, treated it with thorough drainage, and experienced no trouble whatever. No suppuration occurred outside of the joint, and the patient is far advanced toward recovery. The temperature was never elevated above 101° F. He removed the drainage-tube at the end of six days.

MYXOMA-SARCOMA OF THE UTERUS.

DR. F. LANGE presented a specimen consisting of a uterine tumor, and the ovaries removed by supravaginal amputation twenty-four days ago, from a woman forty-four years of age. Microscopical examination showed that the growth was myxo-sarcomatous, large spindle-cells predominating. The entire mass, solid and fluid, weighed at least twenty-five pounds. The following history was given:

An otherwise healthy woman, had borne five children, the last being delivered fifteen years ago. Since that time she has been regular, but the menstrual flow has been somewhat abundant. About five or six years ago she noticed some increase in the size of her abdomen, but it gave her no trouble whatever, and she did not consult any one until a year and a half ago, when she consulted a woman, who by some manipulation caused a watery discharge to take place from the vagina, and this was followed by a decided decrease in the size of the abdomen. After a short period, however, the tumor again increased in size, and she then applied to her family physician, who told her that the growth of her abdomen was due to an increase in the size of the uterus, and that nothing could be done for her. Dr. Lange saw the patient first early in March, of this year, at which time the distention of the abdomen was very great; the largest circumference was one hundred and twenty-two centimetres, due apparently, in great part, to the presence of a solid tumor starting from the pelvis, and located chiefly in the right side of the abdomen. It extended upward to the ribs, the umbilicus was very much distended, and the fact that in the erect posture the umbilicus was pouting, and was collapsed in the horizontal posture, together with the dulness prevailing in the lumbar region which cleared up when the patient assumed the lateral position, led him to the conclusion that there was a certain amount of fluid in the abdominal cavity. The tumor was movable in the lower part, but seemed to be attached at the upper part, where the patient complained of considerable pain. Before the development of this pain she had scarcely complained of any discomfort, except from the size of the tumor. There was a pronounced uterine murmur over the lower part of the abdomen. Afterward, examination showed the vaginal portion of the uterus very much elevated, so as to be scarcely touched with the finger, but movement given to the tumor from the outside was communicated to the vaginal portion. The probe entered the uterus to the depth of three inches without difficulty. The great distention of the abdomen left it in doubt whether cystic degeneration of the right ovary did not exist apart from the tumor of the uterus. An exploratory incision, however, was decided upon. In the apparently cystic portion of the growth a puncture was made, but fluid could not be removed, and subsequently it was proved that it was of a colloid character which could not pass through the canula. The elastic ligature was applied to the cervix extra-peritoneal, the growth was divided a short distance above the ligature, the stump was cauterized, powdered with iodoform, and then covered with peritoneum detached somewhat above. The external incision was about 15 inches long. There were extensive and broad adhesions with the omentum and transverse colon, but they were quite easily separated. Considerable difficulty was experienced when it was necessary to enter the small pelvis, and reach the cervix, but this was overcome by tying the broad ligament with a double

mass-ligature, and cutting across the mass with a thermo-cautery. There was also great difficulty in passing the chain-écraseur about the cervix, which Dr. Lange did previously to the application of the elastic ligature. The tumor was separated at a good distance from the ligature, preliminary to the final treatment of the stump. The bloodvessels within the chain-écraseur and outside of the elastic ligature were tied for the most part separately; some of them, however, were embraced in mass-ligatures; the loss of blood was comparatively insignificant. The peritoneal cavity was carefully cleansed; large flat sponges, dipped in a warm solution of salicylic acid, probably one to a thousand, covered the intestines during the entire operation, so that the hands did not come in contact with them. The wound was closed by at least seventy superficial and deep sutures. In order to form a thick abdominal wall in the middle line, the abdominal walls were brought together by eight lead-plate sutures, introduced at a considerable distance from the cut edges. The peritoneum was sewed up by a continuous catgut suture. Only a very small covering was applied, consisting of a fine layer of gauze, powdered with iodoform, and fixed in position with adhesive plaster. No spray was used, and the peritoneum was kept as dry as possible throughout the entire operation. From the first moment, the patient was treated as though she were suffering from peritonitis—that is, as soon as she rallied from the influence of ether, and the shock and collapse had passed away, cold was applied locally, and opium with quinine was administered by the rectum. Thus far, the progress of the case had been most satisfactory, and Dr. Lange believed that the patient was out of danger. Up to the sixth day she had a good pulse and temperature, but then, without apparent reason, the temperature rose to 104° F. and 105° F., and continued so for two days, while pulse was 70 to 80, and general condition very good. The temperature then subsided, and had not since become elevated. He thought that the elevation of temperature was possibly due to the iodoform, which had been powdered somewhat freely into the abdominal cavity; at least he knew of no other reason to which it could be ascribed. The urine was examined for iodoform, and showed a trace of iodine reaction.

DR. BRIDDON testified to the value of the flat sponges mentioned by Dr. Lange, which he had just employed in a case of double ovariotomy.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Thursday, May 3, 1883.

THE PRESIDENT, R. A. CLEEMANN, M.D., IN THE CHAIR.

DR. WM. GOODELL related the history of

THREE STUBBORN CASES OF VESICO-VAGINAL FISTULÆ SUCCESSFULLY TREATED AFTER THE OPERATION WITHOUT THE USE OF THE CATHETER.

IN the first one, after a non-instrumental labor, lasting from a Tuesday evening, when the membranes broke, to a Friday night, it was found that her urine dribbled away immediately after the birth of the child. The fistula was situated so close to the cervix as to implicate it, and was quite large. Sixteen months after the accident, she was operated on by a distinguished surgeon, whose success in uro-genital fistulæ is very great. He turned the cervix into the bladder, and successfully closed up all the rent save a small portion of it. On this fistula he operated three times without any union whatever. In each instance, the urine dribbled away before the stitches were removed, and on two occasions an alarming hemorrhage came *per vaginam*. This information Dr. Goodell obtained from the surgeon himself.

Early in 1877, Dr. Goodell operated on her at the Hospital of the University of Pennsylvania, and put in Sims' self-retaining catheter. Eight sutures were needed to close the opening. The next day, a hemorrhage from the bladder, possibly menstrual, took place, and lasted several days. A fever also set in, which gave some alarm. When the stitches were removed, very little union was found to have taken place. Four months later, Dr. Goodell operated for the second time; and thinking that the vesical hemorrhage in the preceding operation was caused by the irritation of the self-retaining catheter, he treated her without one. The first twenty-four hours, her urine was drawn off every four hours, but afterwards she was allowed to pass it herself. No hemorrhage occurred, and perfect union took place.

The second case was also one of tedious labor, in which the forceps were not used. The fistula, at first, was a very large one, and was most skilfully closed by an excellent surgeon. A very small fistula, however, remained at each angle of the wound. These defied repeated operations on his part, and the case finally drifted into Dr. Goodell's hands. Twice the latter operated, at his private hospital, on these fistulæ, using the Goodman self-retaining catheter, but each time vesical and uterine tenesmus set in, and the result was a failure. Both fistulæ were then burned with the actual cautery, and one of them closed up; but the larger one resisted this treatment, as well as that by nitric acid. He then operated upon it, a month ago, for the third time, dispensing with the use of the catheter. The lady was instructed to pass her water before the desire was urgent. Neither vesical nor uterine tenesmus occurred. The stitches were left in for fourteen days, and union was complete.

The third case was the result of a short labor, and the cause of the fistula is obscure, as the lady was attended by a midwife, who pulled and tugged away at something after the birth of the child. The late Dr. H. Lenox Hodge had operated five times upon it, closing all but a small fistula which lay at the junction of the neck of the bladder with the urethra. Dr. Goodell closed this fistula at the Hospital of the University three weeks ago with eight stitches, and fearing that the catheter would interfere with union, dispensed wholly with it. The success was complete.

From these cases and from others which he had met with, Dr. Goodell was led to think that the catheter might, as a source of irritation, oftener be dispensed with very advantageously in the treatment of these fistulæ. He cited the practice of the late Dr. Simon, of Heidelberg, who was a very successful operator, and yet rarely resorted to its use. He also called attention to the fact that in these cases, and in the very great majority of the cases he had met with, the forceps had not been resorted to; showing that it was not the use of that instrument, but its neglect, or the delay in its use, that caused the mischief. In fact, he could not recall a case in which the lesion could be attributed to instrumental delivery. In the general experience of surgeons, very small vesico-vaginal fistulæ were harder to cure than moderate-sized ones. One reason for this is attributable to the fact that they usually are found in sites difficult to reach; and another that the operator is unwilling to enlarge the small opening by bold incisions, and fails from too small a denuded surface. Including the one previously referred to, he had closed two of them by means of the actual cautery.

DR. ALBERT H. SMITH remarked that these cases were of great interest. He had been taken by surprise when Dr. Simon announced his plan of treatment without the catheter, as he had been afraid of the

strain on the stitches resulting from the accumulation of urine in the bladder. The presence of the self-retaining catheter must necessarily be a source of irritation and vesical tenesmus. The small holes in its bulb may become occluded by mucus or clot, and then it would act as a plug instead of a drain. In those cases in which the loss of substance in the vesico-vaginal septum has been very great, and the mucous surface of the bladder has been prolapsed into the vagina, the capacity of the bladder becomes small, and it must be emptied frequently, or the tension on the stitches becomes too great.

He had been gradually led to the conclusion that it would be better not to use the catheter after trachelorrhaphy and perineorrhaphy, unless called for by special circumstances. There are cases in which, in consequence of mental influence, or the effect of position, the patient cannot pass her water for weeks after labor in which no injury or long or undue pressure has occurred.

DR. R. P. HARRIS had recently operated for the restoration of a very long perineum; the last stitch was almost on a line with the orifice of the urethra, and the nurse was not able to introduce the catheter. He placed the patient in a sitting position to pass her water, and used a male catheter, tied on the tube of a Davidson syringe, to wash out the vagina.

DR. GOODELL is by no means a convert to treatment in this class of cases without the employment of the catheter. He has been too successful with it. He prefers the Goodman self-retaining instrument; but he always makes certain that it did not impinge on the wound. He has recognized the influence of mind and of position on the ability to pass water, and he thinks the use of ergot, so general before the third stage of labor, is one cause of the difficulty, as it is quite possible that it may cause a spasm of the urethral constricting fibres. He would like to dispense with both catheter and syringe after perineorrhaphy, as he has found injuries to the interior angle of the wound by the syringe and the fingers of the nurse while introducing the catheter. He has been in the habit of putting one stitch through the sound skin above the denuded surfaces to prevent this injury. In one case recently, the Goodman catheter slipped out twenty-four hours after perineorrhaphy, and he did not replace it, the wound healing. He always uses the catheter after trachelorrhaphy.

DR. WM. GOODELL also exhibited

TWO OVARIAN TUMORS, ONE OF THEM OF DOUBTFUL CHARACTER.

The one of doubtful character was removed from an unmarried woman, aged 27, who had not menstruated for over a year. It was first discovered nine years ago, but gave no trouble until two and a half years ago, when ascites set in. She had been tapped fourteen times when Dr. G. first saw her. She was very thin, pale, and so weak that she had to keep her bed. He recognized a hard tumor floating in the ascitic fluid, giving the feeling of ballottement, and diagnosticated it as either a solid ovarian tumor or a pedunculated fibroid.

On the 18th of last April, he removed it at the University Hospital, and found it to be a large, solid nodular tumor of the right ovary, with evidences of papillomatous degeneration. It had merely omental adhesions, and had a long, slender pedicle twisted many times on its axis. It was evident that the ascitic fluid was secreted directly from the tumor, and did not come from pressure on abdominal veins, or from irritation of the peritoneum.

The other cyst was removed also at the Hospital of the University, and on the same day, from a married woman, aged 26, who noticed it two months after her marriage, and about four months ago. The cyst was as large as the adult head, and was apparently attached to the womb, which was drawn upwards, and gave a measurement of four inches. It was operated on early, because it caused great vesical disturbance. The lower portion of the cyst was found enveloped in the broad ligament, close up to the womb, and had to be enucleated. It was this condition that gave the symptoms of uterine attachment. The cyst was that of the left ovary, but as the right ovary also presented tokens of degeneration, it was also removed. Both women recovered promptly, although the first one had, on the third day, a severe attack of mumps, which appears to be prevailing in this city as an epidemic. The ascitic fluid, which was straw-colored and syrupy, was not examined microscopically.

DR. M. O'HARA wished to know how Dr. Goodell could decide quickly between mumps and septic parotitis. He also spoke of the reflex action of the sexual organs as shown by the frequent occurrence of salivation during pregnancy. In a recent case of cancer of the rectum, the first symptom observed was excessive secretion of saliva.

DR. ALBERT H. SMITH remarked that mumps was a very interesting and very perplexing disease. He has seen cases of extension of the disease without retrocession, in adult women to mastitis and ovaritis, the swelling of the parotid gland being rapidly followed by the involvement of the sexual glands, the inflammation of the ovaries being accompanied by local peritonitis. A singular question was raised by the case of a young man, who went to Florida directly after marriage, and on the return trip by sea experienced a severe attack of mumps; it was complicated by orchitis, the inflammation being of high grade with great increase of temperature, and rapid pulse. No atrophy of the testicles has occurred, but the union has been sterile, and there is no known fault on the part of the wife. The semen has not been examined microscopically to ascertain the presence of spematozoids. The mastitis accompanying mumps has never in Dr. Smith's experience run into suppuration, but is accompanied by febrile action of a high grade. He has seen the ovary the original point of attack, the inflammation of the mammary gland being later. It is a marvel of pathology that this disease which affects in childhood the salivary glands only, should in adult life affect the sexual glands also. He has never seen a case of atrophy of the testicles following mumps.

DR. GOODELL recognized mumps in this case by his experience in two previous cases of mumps with severe symptoms, in adults. The pulse does not become so frequent as in septicæmia, and the eye remains clear and does not acquire that glassy appearance so indicative of a fatal issue. Dr. Goodell has never seen the involvement of the breast and ovary. A peculiar relation between the sexual organs and the glands of the neck is shown by a habit of the Roman matron, who measured the throat of her daughter before and after the night of her marriage to ascertain if the young husband had properly performed his marital duties, and if they had been properly received.

DR. ALBERT H. SMITH exhibited a set of hard-rubber

URETHRAL DILATORS.

The set consists of ten pieces with two handles, into which they can be screwed; the smallest bougie is twenty millimetres in circumference at the point, and twenty-eight millimetres at the largest part, the tapering in each bougie being eight millimetres, and a difference of six millimetres between each one and the largest circumference of the next in the scale. The largest one is eighty-two millimetres at the largest part

and would be useful as a rectal dilator. He had been very much surprised at a statement made by Dr. Emmett at the last meeting of the Gynecological Society, in Boston, that dilatation of the urethra almost universally causes laceration, and is followed by permanent incontinence of urine. Dr. Smith has been in the habit of doing it frequently and fearlessly, without hesitation, not only in diseases of the urethra and bladder, but for exploratory purposes and for the removal of stone, but also as a step in the operation of anterior elytrorrhaphy; that by means of a finger in the bladder he may judge of the thickness of the walls in denuding the vaginal surface and place his sutures satisfactorily. He has never had incontinence of urine to last over twenty-four hours from this procedure.

DR. R. P. HARRIS has seen a large number of dilatations of the urethra without any bad effect. He would consider the method of Dr. Smith's better than any other plan, as it would make a perfectly even and uniform pressure on every portion of the urethra, with a very gradual action, free from the dangers incident to the opening of any form of instrument with blades.

DR. GOODELL was much obliged to Dr. Smith for exhibiting these instruments, and would get a set of them. He has entirely dropped Sims' dilators, and has for some time been using his little finger as the best dilator. He has not had any trouble from laceration or incontinence. In one case in which he resorted to dilatation and treatment to the mucous surface of the bladder as a cure for cystitis following labor, incontinence remained for a long time, but gradually disappeared. He knew of laceration and incontinence in two instances resulting from the use of the thumb as a dilator. Dilatation alone is a good treatment for many cases of irritable bladder.

DR. WM. H. PARISH narrated the case of a widow operated on by Dr. Goodell by dilatation for the relief of a very aggravated case of irritable bladder, the result of a gonorrhœa contracted years before from her husband, and which had been followed by cystitis. It was greatly relieved for several months, but not cured, by dilatation, but the relief was only temporary. The patient passed under the care of Dr. H. Lenox Hodge, who cauterized the urethra by means of Paquelin's cautery. In consequence of the illness and death of Dr. Hodge, she came again under the care of Dr. Parish, who commenced treatment by the injection of a solution of nitrate of silver, very strong at first but weaker on subsequent applications. The trouble has passed entirely away. There are two causes of fissure in dilatation, the first is too rapid expansion of the dilator; the second, changes in the mucous membrane, as from inflammatory action, particularly if caused by gonorrhœal poison.

DR. CHAS. H. THOMAS, had lately procured a set of nickel-steel instruments of about the same taper, and for the same purpose as those exhibited by Dr. Smith. The set consisted of sixteen pieces, there was one and a half mm. as the scale, and each dilator tapered five mm. from the point to the largest circumference of the shank, they ranged from twenty-five to fifty mm. He has tried in some cases, using every second instrument, making rises of three mm., but has found that the pain was increased by so doing. He has never known of a case of incontinence caused by dilatation, but has heard of such from the hands of two celebrated surgeons of this city. He thinks dilatation to the size of the finger a good treatment for the relief of irritable bladder in connection with irritation of the urethra and neck of the bladder. He related the history of two cases, in which this condition was complicated and made persistent by sphincterismus of the sphincter-ani muscle; dilatation of the urethræ in these cases, although a benefit, did not cure the trouble, but when to this was added dilatation of the sphincter ani, so that two fingers could be introduced, back to back, and a good dilatation secured, the cases were permanently cured.

DR. B. F. BAER has practised dilatation of the female urethra a number of times, and has had no instance of continued incontinence. He would, however, question the propriety of ever using a large-size dilator, except for the purpose of removing a calculus from the bladder, and even in that case, he thought it might be better to allow the stone, in the grasp of the forceps, to finish the dilatation than to use mechanical dilators to secure the full extent needed. In one instance, incontinence lasted several weeks after dilatation, but final recovery was complete, solutions of carbolic acid having been applied in the meantime for the cure of irritability of the bladder and urethra.

DR. PARISH would like to hear from Dr. Smith respecting the indications for probable success in treatment by dilatation of the urethra for the relief of irritation of the bladder.

DR. SMITH, in reply to Dr. Baer, remarked that no cavity of the body should ever be dilated beyond the actual necessities of the case; such a principle is unquestionable; but no form of dilator could be worse than the irregularities and roughness of a calculus, increased in size as it would be by the grasping forceps, which would present but two points of contact with the urethra, and render laceration quite probable. In a patient recently under his care, he had reason to suspect the existence of papillomatous growths on the mucous surface of the bladder. He dilated the urethra, using the largest size of Sims' dilators, and completing with a Molesworth dilator, expanded very slowly. He was able to evert the bladder through the urethra, and removed the vegetations by means of scissors. There was no laceration nor incontinence resulting from this procedure. The danger is in too great haste. In reply to Dr. Parrish, he said that dilatation is usually resorted to for exploratory purposes; removal of stone; growths of the vesical wall, or to ascertain the thickness of the wall of the bladder, and to introduce a finger into that viscus to guide the sutures in plastic operations upon the vagina. Irritability of the neck of the bladder can generally be relieved by dilatation, but it sometimes fails to cure. Dr. Smith prefers hard rubber to plated metal as the material for the dilators; it is lighter in weight, is not liable to corrosion, and is more easily kept clean. He thinks the multiplicity of instruments in Dr. Thomas' scale a disadvantage, and that time is lost and irritation caused by introducing several instruments in place of allowing one to remain a longer interval.

CONNECTICUT MEDICAL SOCIETY.

Ninety-second Annual Convention, held at Hartford, May 23 and 24, 1883.

(Specially reported for THE MEDICAL NEWS.)

THE annual convention of this Society, one of the oldest medical organizations in the country, convened at Hartford, on May 23, in the Common Council Chamber, at 3 o'clock.

THE PRESIDENT, WM. G. BROWNSON, M.D., of New Canaan, addressed the Society briefly, in accordance with a by-law which makes it his duty to bring to the attention of the Fellows any subjects that he deems worthy of their attention and action. The business which is transacted the first day is in the hands of delegates from each of the eight county societies, called Fellows, and certain officers who act *ex-officio* as Fellows. Thus the Presidents of the county societies are Vice-Presidents of the State society. There is

no separate membership, and in order to join the State society, one must be a member of some county medical association; this makes him a member of the State society. After he has once been elected as a Fellow, he retains all its privileges, except that of voting.

THE PRESIDENT'S ADDRESS.

After welcoming the members, and referring to the advances the Society had made, and the prominence it had attained, he made the following recommendations:

1st. That the number of Fellows should be based upon the number of taxable members, and perhaps the number allowed to act as delegates should depend upon the amount of the tax collected at the date of the meeting. While the membership has greatly increased, the number of delegates remains the same as it was fixed in 1870.

2d. As there is some question whether the Society's charter was not inadvertently repealed at the time of the revision of the charter of the Medical Institution of Yale College, he advised that a committee be appointed to determine this point, and offer such suggestions for a revision of the charter and by-laws as they might deem expedient.

3d. That all ex-presidents should be made Fellows, and constitute a Board of Councillors, who should have all matters of ethics and discipline under charge, should secure proper papers for the annual Convention, and perform such other duties as might be placed upon them.

4th. With reference to the Secretary, he advised that the office be made permanent, and a salary be paid, commencing with fifty dollars a year. The Treasurer also should receive compensation. In this connection he announced with regret that the present Secretary declined to continue longer in office, from the press of other duties which required more and more of his time and energies. He paid a glowing tribute to the fidelity of Dr. Chamberlain, and to the success of his administration of the affairs of the Society.

5th. He deprecated the indiscriminate use of new remedies, and suggested that the Society add to its standing committees, one on new remedies, who should report each year upon the claims of such as had proved to be of value and efficiency.

6th. The State Board of Health was commended and its advice concerning public funerals in death from such diseases as diphtheria, endorsed; and the advisability of a law on the subject mooted. The movement for a higher standard of medical education was referred to, and the action of the Yale Medical Department in this direction was commended.

In closing, he alluded to the discussions concerning the Code, which he considered as an instrument that had nearly outlived its usefulness. The action of the Legislature in refusing to repeal the law concerning compulsory vaccination of school-children, was commended, and the Society congratulated upon the new coroner system. The honored dead of the past year were fittingly alluded to, and the examples of their lives as worthy of imitation.

On motion of DR. WILE, it was voted that a committee be appointed upon each recommendation of the President; these committees to consist of three, and to be appointed by the President.

THE LEGAL STATUS OF THE SOCIETY.

DR. CHAMBERLAIN remarked that the subject of the legal status of the Society, and the revision proposed to be accomplished, was so important, that a larger and more representative committee should be appointed. This committee should be made up of one from each county. He moved a reconsideration of that part of the motion relating to this subject, which was voted. This committee, it was moved, should have power to act without reporting to the Society, and to secure a charter from the Legislature.

PROF. M. C. WHITE objected to any such action, stating that the charter of the Society was repealed through the negligence of the Society's committee; that this committee had been empowered to act without reporting to the Society, and such was the result. The Society and Medical Department of Yale College were incorporated together. The charter of the Medical School, as revised in 1879, was extremely unsatisfactory to himself and to others, especially in the power there granted for a dissolution of the relations between the Medical School and the Society by mutual consent, without any recourse to the Legislature. Had the committee been obliged to report to the Society, different action would have been taken.

DR. CHAMBERLAIN agreed with Prof. White that the committee should report to the Society, but thought the only mistake about the revision was in that section that repeals the charter. By request he read the offending section, which sweeps out of existence the whole of the incorporating act, instead of that part relating to the Medical School alone, then under revision. If the section was in the act when received from New Haven and submitted to the committee, it escaped notice, because an identical copy was in the old charter, and its transfer to the new was supposed to mean nothing more than a repeal of conflicting portions; no such section was read or discussed at the sessions of the joint committees. He stated that the rights of the Society were fully guarded, and in case the relations between the Society and the Medical School were dissolved, he did not think this Society would be left at a disadvantage.

There was considerable discussion on the need of a charter, and the relations of the Society to the School. It was expected that some definite action would be proposed for a separation of the School and Society, which, at present, grant degrees conjointly.

After various measures had been proposed, the acceptable portions were incorporated into the following resolution presented by Prof. Carmalt, which was adopted unanimously.

Resolved, That a committee consisting of one member from each county, to be selected by the Fellows from the respective counties, be appointed to take into consideration the legal status of this Society, with power to employ counsel, and to report at a special meeting of this Society, to be called by the President.

The following were appointed the Committee under the above resolution:

Drs. C. W. Chamberlain, W. H. Carmalt, F. N. Braman Geo. F. Lewis, H. W. Buel, E. A. Hill, G. W. Burke, and A. R. Goodrich.

THE REJECTION OF A VOLUNTARY ESSAY

having been complained off, the subject was referred to the Committee on County Resolves, who reported substantially as follows: That it was the duty of the Publication Committee to decide such questions, but that the merits of the paper should be the criterion, not its accord with the opinions of the Committee.

AN AMENDMENT TO THE BY-LAWS

assigning duties to the censors of County Societies was formally reported and adopted.

The following amendments for next year were proposed, and by rule lie over a year:

1. That no voluntary paper be published that has not been read before some County Society, and endorsed by it.

2. Each County Society shall elect its member of the Nominating Committee, and also an alternate.

3. That every resolution shall be offered in writing, without any erasures or interlineations.

4. That all remarks made in relation to any subject shall be written out either before or after they are made, and that the Secretary be authorized to procure suitable means for carrying this rule into effect.

LEGISLATION ON THE PRESIDENT'S RECOMMENDATIONS.

The following propositions were made in accordance with the recommendations of the President:

That there be a board of councillors established, composed of ex-presidents, who shall be permanent Fellows.

That the Secretary shall be a permanent officer, with a salary of fifty dollars.

That the number of elective Fellows shall be increased to fifty-five.

These propositions will be acted upon next year.

PUBLICATION OF FORMULÆ OF PROPRIETARY MEDICINES.

Upon motion of DR. CHAMBERLAIN, it was voted that the Secretary memoralize the Legislature on behalf of this Society, for the passage of a law requiring that no patent or proprietary remedy shall be sold in this State, unless the formula of its construction be plainly printed on the label. That there shall be a heavy fine for evasion of this law, and if analysis shows any considerable difference from the alleged formula.

The Nominating Committee reported the following, who were duly elected

OFFICERS FOR THE ENSUING YEAR:

President.—ELISHA B. NYE, M.D., of Middletown,

Vice-President.—B. N. COMINGS, M.D., of New Britain.

Secretary.—DR. S. B. ST. JOHN, of Hartford.

Treasurer.—DR. E. P. SWASEY, of New Britain.

Committee on Matters of Professional Interest.—DRS. W. C. WILE, J. H. GRANNIS, and E. C. KINNEY.

NO DELEGATES TO THE NEW YORK STATE MEDICAL SOCIETY.

When the nomination of delegates to the New York State Medical Society was in order, it was moved to lay the nominations on the table. After some debate, which was allowed rather as a matter of explanation, such action was taken, on account of the present relations of the New York State Society to the American Medical Association.

THE ANNUAL TAX.

The usual tax of two dollars, payable on and after June 1st, was assessed, and it was voted to publish seven hundred copies of the proceedings.

THE TREASURER'S REPORT

was then presented, and after comparing it with the accompanying vouchers, it was declared correct.

The Treasurer, Dr. Swasey, reported that the increase of receipts over last year was $50, decrease of expenses $75, balance in the treasury $640.

There were three counties that showed no arrears, and none that owed on any except the tax of last year. There was about $100 still due, half of which was from Fairfield County. The satisfactory condition of the treasury was largely due to the efficiency and energy of Dr. W. H. Holmes, of Waterbury, who had collected all the arrears of taxes in New Haven County, so that, although, the amount left uncollected is larger than last year; the general result is as favorable.

THE COMMITTEE ON HONORARY MEMBERS

reported favorably on the name of Dr. John S. Billings, Surgeon U. S. A., who was unanimously elected. They reported the names of Dr. James E. Reeve, West Virginia, and Prof. T. A. Emmett, of New York, for election next year.

THE LIBRARY AND MUSEUM OF THE SURGEON-GENERAL'S OFFICE.

The following preamble and resolutions were adopted on motion of DR. CHAMBERLAIN:

Whereas, The Army Medical Museum and Library of the Surgeon-General's Office in Washington are recognized by the profession as the most valuable collections of their kind in the world, and the medical profession, not only in this State, but everywhere, is interested in their preservation, and

Whereas, We have observed with regret that they are still liable to destruction and irreparable damage by reason of the insecurity of the building in which they are placed, which is also not suited for any such purpose. Therefore be it

Resolved, That, in the opinion of this Society, the importance of these collections demands from Congress such action as will secure the safety of the books and specimens, render them easy of access, and amply provide for the future wants and uses of the Museum and Library; that an appropriation of sufficient amount to build an adequate fire-proof building, both for the present absolute necessities and for future developments should be made.

Resolved, That this Society would regret to see any separation of these two collections, or any change in the present management, as detrimental to both and an injury to the cause of medical education throughout the entire land.

Resolved, That a sufficient annual appropriation should be made, to allow the purchase of all new medical books and journals, wherever published, and that, in doing this Congress promotes the best interests of the medical profession in this country. That the appropriation should be a liberal one, commensurate with the interests involved, and bear a just relation to the claims of the profession, which are too often ignored.

Resolved, That this Society is especially interested in the *Index Catalogue* of the Library of the Surgeon-General's Office, a work of inestimable value, which should receive substantial aid from Congress, and be pushed to a speedy conclusion.

Resolvèd, That a copy of these resolutions be sent to every member of Congress from this State, and the members be requested to use their personal influence with those members of Congress whose acquaintance they may have.

It was voted to endorse in general terms the plan of a

MEDICAL REGISTER OF NEW ENGLAND,

as proposed by the Massachusetts Medical Society, but to refer the details to the County Societies.

The Committee on Revision of the

LAW RELATING TO CORONERS

reported that, while nothing had been done collectively, all the members had worked to secure the results attained, of which the Society might well feel proud.

DR. CHAMBERLAIN spoke of the work done by the State Board of Health, and by Drs. Porter and Cleveland, both of whom had labored very efficiently, and, learning the merits and deficiencies in the Massachusetts law by personal study on the field of its operation, had enabled them to improve upon that law in several practical points.

The Committee on

THE CODE OF ETHICS

reported that if any changes were to be made, they should originate in the American Medical Association, and not from a State society.

The report was accepted, and the Committee discharged.

The convention then adjourned, for a reception at the United States Hotel, given by the Hartford City Medical Society, which was largely attended.

MAY 24TH.—SECOND DAY'S SESSION.

THE SECRETARY'S REPORT

stated that the history of the year had been one of uninterrupted prosperity; the condition of the Society had never been more satisfactory. The losses by death had been unusually heavy, both in numbers and men. The new members number thirty-one. The Society now numbers four hundred and sixty. In closing, he congratulated the Society upon its prosperity, the zeal of its members, and the harmony that so generally prevailed.

RECOGNITION OF THE SECRETARY'S SERVICES.

PROF. WHITE moved that the thanks of the Society be tendered to Dr. Chamberlain for his long, faithful, and arduous services for eight years as Secretary.

DR. WILE moved, as a substitute, that a committee be appointed to draft suitable resolutions and have them engrossed and presented to the retiring Secretary, as a slight expression of our recognition of the value of his services. This was passed unanimously, and the President appointed Drs. W. C. Wile, M. C. Hazen, and Geo. L. Porter.

THE ANNUAL ORATION

was then read by the PRESIDENT, subject—*The Country Doctor*, in which he presented a graphic pen-picture, in poetical form, of the checkered life of the country doctor.

Upon motion of DR. PORTER, the thanks of the Convention were voted the President for his interesting address, and a copy requested for publication.

The President then presented to the Convention the following

DELEGATES FROM OTHER STATES,

who addressed the Society briefly, and expressed the greetings and kind wishes of their respective societies:

Dr. G. J. Townsend, from *Massachusetts;* Drs. A. G. Browning and Charles O'Leary, from *Rhode Island.*

Dr. St. John read a telegram from Dr. D. C. English, of New Brunswick, expressing the salutations of the Medical Society of New Jersey, and regretting that his State was not represented.

Dr. T. D. Crothers presented credentials from the American Association for the cure of Inebriates, and offered a paper on *Inebriate Automatism*, which was referred to the Publication Committee.

Dr. M. H. Henry, of New York, and Dr. G. Sawyer, of Bedford, New York, were invited to be

GUESTS OF THE CONVENTION.

DR. HENRY offered a paper on

THE TREATMENT OF VARICOCELE,

describing its pathological anatomy, the dangers of the old methods of operation, and described the operation which goes by his name, exhibiting his clamp and describing its use. He stated that he had statistics of one hundred and fifty successful cases; not selected, but consecutive cases; no failures. The result also was more satisfactory and permanent than that from any other method.

DR. CHAMBERLAIN briefly described two cases of Henry's operation, performed by Dr. Geo. C. Jarvis, in which he had assisted.

PROF. M. C. WHITE then exhibited

A MICRO-SPECTROSCOPE

of his own invention, and, after a condensed analysis of micro-spectroscopy, described the merits peculiar to his instrument. It consists in the introduction of an eye-piece micrometer in the micro-spectroscope, placing above the spectroscope a non-magnifying telescope, the eye-piece and field-piece of the same power.

DR. W. C. WILE reported an unsuccessful case of

EXTIRPATION OF THE UTERUS,

performed as a forlorn hope at the solicitation of the patient, who lived five days after; the specimen was shown. The *status* of the operation was not settled, he stated, but in selected cases he considered it a justifiable operation, and, also, where it promised relief from extreme agony, as in the case upon which he operated.

ILIAC ABSCESS MISTAKEN FOR SPINAL MYELITIS.

He also reported a case of a man, aged 45, one leg contracted from an arrested hip-joint disease when a boy, who had been treated by specialists for three months for spinal myelitis, the typical symptoms of which he then presented. Dr. Wile discovered an abscess in the iliac region, which the patient would not let him open. When it opened it discharged profuse quantities of rather sanious pus. As he suffered excruciating pains afterward, it was determined to enlarge the opening and remove the dead bone suspected to be present. When the joint was cut down upon, it was found that the head of the bone was absorbed. Several inches were exsected. Upon tracing the abscess it was found to burrow up to the lower angle of the scapula. The patient made a good recovery.

DR. W. C. BURKE, JR., reported a successful case of

EXTIRPATION OF THE UTERUS,

performed some months ago. He exhibited an instrument, cleverly made out of copper wire, by the aid of which he placed and tied his stitches without making undue traction upon the broad ligament; dragging down the parts to get at them, he regarded as one of the principal sources of danger.

DR. GEO. L. PORTER related a case of

EXTRA-UTERINE PREGNANCY.

The body of the fœtus was in the Fallopian tube, the short circumference of the tumor in the tube was twelve inches, the long twenty-two inches. The head extended out of the Fallopian tube, the fimbriated extremity of which encircled the neck. The woman died of asthenia.

PROF. WHITE related the following

UNIQUE CASE OF STONE:

At a post-mortem recently, he found twenty-two calculi in the bladder, of varying sizes, they lay mostly in a cul-de-sac behind a very much enlarged prostate. Outside the bladder in the cellular tissue were fifteen concretions, some of them the size of a pea. One examined carefully was found to be made up of phosphate and carbonate of lime.

DR. GEORGE W. PARMELE, of Hartford, read a paper on

DENTISTRY AND THE TREATMENT OF TEETH,

contrasting the modern scientific mode of preservation with the old remedy in *all* cases—the forceps. He explained the relations between the teeth and digestive and nervous troubles, diarrhœa and dyspepsia, and

showed the relation between imperfect and diseased teeth to many conditions and cases of illness, to which the teeth were not suspected of bearing the least causative connection; and that many other troubles besides neuralgia, the only one generally recognized, are due to poor teeth.

THE EARLY RECORDS OF THE SOCIETY.

DR. G. W. RUSSELL spoke of the early history of the Society, and moved that the Secretary condense the records and transactions of the past twenty-five years, and have them printed. He himself would be responsible for one hundred dollars of the expense. The motion was adopted.

A resolution was also passed instructing the Secretary to write to the county societies and ascertain whether they would bear a share of the expense of printing a revised account of the records and papers of the Society from 1793 to 1830.

DR. W. H. HOLMES read an essay on

ASPIRATION OF THE CHEST IN PLEURISY,

with illustrative cases. The advantages of the operation, and the results of delay or neglect, were considered.

DR. F. N. BRAMAN then read a paper on

COMPLICATIONS OF LABOR.

He discussed version in hour-glass contractions. He advocated the use of a fillet around the body to assist in rotation, and enable the operator to have entire control of the child.

PROF. BECKWITH stated that where he lost cases of complicated labor from peritonitis, he now always considered that some of the tissues of the mother had been injured. The fillet around the body, as described by Dr. Braman, was certainly original; so far as his reading extended at least, he did not recall having ever before seen a description of any such use. But the fillet around the shoulders, as described by Barnes in his *Obstetric Operations*, was a quite well-known and often practised procedure. He considered that all that could be accomplished by the fillet around the body could be equally as well secured by the fillet around the shoulders, as the child's tissues would not sustain a pressure above a certain amount; any greater force was no gain.

DR. BRAMAN stated that the object was not to obtain more force, but to obtain control of the body of the child completely, which could be done by no other method.

DR. A. BEARDSLEY then gave a report of his

FIFTY YEARS' EXPERIENCE IN TREATING INTERMITTENT FEVER.

Eschewing any discussion of theories of causation, or reasons for its reappearance, he at once presented his method of treatment without quinine. Briefly, it is as follows: First, brisk alterative purgatives, aloes, blue-mass, and capsicum in equal parts, made into pill-form, or calomel in place of the blue-mass. An alterative purgative was to be taken at the outset, and repeated as the nature of the case demands. This was to be followed by an aromatic bitter, and perhaps an alkali with it, or in combination with boneset tea, drunk very freely, was an element in the cure not to be overlooked. He stated that this method had been very satisfactory in his and others hands, and was often successful where quinine had utterly failed, and that, too, where it had been pushed; indeed, as far as twenty-grain doses three times a day, or even oftener.

The remaining papers and the report of the Committee on Examination at Yale Medical Department were ordered read by title, and referred for publication.

The Society then adjourned for

THE ANNUAL DINNER

at the United States Hotel, after one of the most successful meetings held for many years, both in numbers, enthusiasm, and value of literary exercises.

MEDICO-CHIRURGICAL SOCIETY OF MONTREAL.

Stated Meeting, April 27th.

(Specially reported for THE MEDICAL NEWS.)

THE PRESIDENT, R. A. KENNEDY, M.D., IN THE CHAIR.

CASE FOR LOCALIZATION.

DR. OSLER presented a patient with the following history: Francis ——, aged 41, married fifteen years. Not known to have had syphilis, though he lost one child shortly after birth with a skin eruption. Has enjoyed good health, with exception of present trouble. For six years he has had epileptic fits; at first at rare intervals—one in three months—but now one every fortnight. Liable to have them at any time if much excited. They are, his wife says, confined to the right side, towards which, also, he tends to fall. Not known whether they begin in hand or foot, as he has not had a fit since under observation; always loses consciousness. Nearly two years ago he began to have trouble in the right leg, jerkings and stiffness, which have steadily increased. The right arm was also weak, and for the past five months the speech has been affected. His memory is not so good as it was, and at times he is irascible. He has had two injuries to the head; the first when a lad of seven or eight, which has left a long scar on the right side, high on the parietal bone. There is no adhesion of the skin and no depression. The other was received by the fall of a scantling, seventeen years ago, and is a flat scar a little behind bregma on left parietal bone. It is not depressed, and the skin not adherent. At present, nutrition of muscles good; he walks with difficulty, owing to stiffness of right leg, in which the spastic gait is well marked. Reflexes greatly increased in the leg. Knee-cap somewhat exaggerated also in the left. Right arm does not appear much affected, but he says it feels weak. Grip is good; dynamometer shows it to be a little weaker than the left. Slight paralysis of lower facial muscles; tongue deviates strongly to the right, uvula drawn towards the left. Speaks with hesitancy, and is often at a loss for a word. No impairment of sensation. No optic neuritis or retinitis. The patient's head was shaved and Broca's lines drawn, in order to define the exact position of the old injury on the left side. It is just behind the bregma, and would correspond on the cortex of the brain to the hinder part of the superior frontal convolution.

The symptoms point to a lesion of the motor area on the left hemisphere, situated about the upper end of the fissure of Rolando, along the ascending frontal and extending to the inferior frontal sinus. The character of the convulsive seizures, unilateral, the monocrural rigidity, the dissociation of the paresis, leg, and face, and gradual extension, point to a cortical lesion; but whether connected in any way with the old injury is somewhat doubtful. The question of trephining in such a case naturally suggests itself, and may come after further study of the case.

DR. RODDICK stated that he had known the patient for some time, and he had suggested the advisability of trephining at the site of the old injury but had been overruled by his colleagues.

CHYLURIA, NOT PARASITIC; AUTOPSY.

DR. MCCONNELL read the report of the case. A woman, aged 33, native of the Province; married ten years, two children. Eleven years ago she noticed that the urine was milky. Had been healthy up to that time, but ever since had not been so strong. The white appearance of the urine has persisted with occasional periods of intermission, two of which were while she was pregnant. Came under observation on October 27th. Was pale, anæmic, moderately emaciated. Appetite good, is constantly hungry, and eats five or six meals a day; sleeps well; bowels very constipated. Has to make water very frequently, nearly every half hour, and it is of the color of milk. Sometimes very painful to pass from the presence of thick, clotted portions. A sample passed was quite fluid when fresh, but in a few minutes a large part of it curdled. Examination of abdominal organs negative. In chest, râles at apices of lungs. On three occasions the blood was carefully examined by Dr. Osler and myself, a number of slides at a time, and the blood taken after midnight, but no filarian embryos were ever discovered. The quantity of urine passed was estimated for several days, and ranged from six to eight quarts; often the clots were blood-stained. Microscopically, it presented fatty molecules, like the molecular base of the chyle, a few blood-cells and leucocytes. Repeated examinations failed to detect any parasites. The condition of the patient grew gradually worse through the winter; the cough became more distressing, and the digestion much impaired. Death took place on the 5th of March. For three days before dissolution, the urine was bloody and not so abundant. The *post-mortem* was held on the 18th inst., the body, which had been in vault of the cemetery, was in a good state of preservation. A careful dissection was first made of the thoracic duct and receptaculum, but, as the specimen shows, it appeared perfectly normal, perhaps a little small, but pervious throughout, and contained a bloody lymph. No dilated lymph vessels about the kidneys, or any special connection between venal and abdominal lymphatics. The mesenteric and retro-peritoneal glands were a little enlarged and firm, and, on section, presented opaque areas of fatty degeneration. No caseous or calcareous glands. Lacteals not distended. Kidneys were of average size, capsules detached easily, substance a little blood-stained, but looking very natural. Ureters normal. Bladder contained six or eight ounces of bloody fluid, which had clotted. Mucosa normal. Inguinal and pelvic lymph glands not enlarged. Tubercular cavities at apices of lungs, and a few ulcers in the ilium. The lymph glands, retro-peritoneal tissues, mesentery, and kidneys were subjected to prolonged microscopical examination without producing a trace of anything parasitic, or, indeed, of anything which threw any light on the nature of the affection.

DR. RODDICK asked if it were not possible that in the course of the disease the filaria might disappear?

DR. OSLER thought it not probable, without leaving some trace of the presence of the adult worms which live in and about the lymph glands in pelvic and peritoneal tissues. The value of this case was considerable, as it showed that we should not regard, as some recent writers do, chyluria and the filarian disease as identical.

INFLAMED UMBILICAL HERNIA.

DR. F. W. CAMPBELL read the notes of the case: Stout woman, aged 64, had had an irreducible umbilical hernia for fifteen years. Had been seen four years ago, with a painful attack in the hernia which subsided in a few days. On the morning of April 9th, was sent for, and found her suffering great pain in the sac. The pad had got off, and without waiting to replace it, she had jumped out of bed, and was at once seized with severe pain. The hernia has been getting a little larger of late, and the pad was too small. It was at once reduced to the usual size without difficulty, but the pain continued. Liq. opii sed. was given. An enema brought away many scybala. In the afternoon, she was not so well, and vomiting set in. On the 10th she was easier, and on the 11th pain was well kept down, but the vomiting was excessive. An injection brought away a large fecal stool. 12th, had a restless night; pain has returned, but not so severe.

Was seen by Drs. Howard and Fenwick, but it was decided that the symptoms scarcely justified an operation. Through the 13th and 14th, she kept about the same; the vomiting not so frequent; and on the evening of the 14th she seemed very much better. Early in the morning of the 15th, she got much worse, became cold, sank rapidly, and died in a few hours. The autopsy showed a thin-walled umbilical sac, not inflamed. In it were two coils of intestine; one, about thirteen inches in length, was dark-colored, deeply congested, and inflamed; the other, nine or ten inches in length, was natural looking, though a little swollen. Two fingers could be passed into the ring; there was no strangulation. There was no adhesion of the bowel to the sac. The inflamed portion of the bowel presented two flat bands of slightly thickened peritoneal tissue, where it has been probably for years in contact with the ring. The inflammation had extended along the adjacent coils in the abdomen for a few inches. When slit open, mucosa intensely inflamed, of a deep, livid-red color, and covered with closely adherent flakes of croupous exudation. Heart fatty. No other changes of note.

A difference of opinion had existed regarding the existence of strangulation in this case, and the propriety of operating. From the post-mortem appearance, it did not seem probable that nipping of the bowel had occurred, as the ring was large, and a healthy coil was in the sac. It may have been simply the result of a primary inflammation of the hernial coil, which had evidently been in the sac for years, as it was dark with pigment. One of the most inexplicable features of the case was the the sudden heart failure; but she had been taking very little nourishment, and the vomiting had reduced her strength very much.

CANCER OF THE STOMACH.

DR. WOOD presented the specimen and narrated the case. A woman, aged 55, had suffered for a year or more with dyspeptic symptoms, and two months ago had vomited a small amount of blood; had lost flesh, but was not cachectic. No tumor of abdomen could be made out, but cancer of the stomach was suspected. The details of the last week of her illness are as follows: On April 14th, 15th, and 16th, she had a good deal of nausea and vomiting; on the 17th, she went to bed and I saw her for the first time in several weeks. There was vomiting and considerable epigastric pain; pulse about 90. On the 18th, she was easier. 19th, much worse; she had fainted in the night; pulse weak, 115; face pale, feet cold, vomiting frequent. In the evening the temperature was 101°, pulse 120; the pain in abdomen was more diffuse, and there was considerable distention. On the 20th, condition did not improve, though, under opium, the distress was not so great. On the 21st, prostration more marked, and the next day the vomiting was distinctly fecal and frequent. Death on the 23d.

At the autopsy, the small intestine from an inch or two below the duodenum to within two inches of the valve, was dark in color, distended, and covered in places with a thin sheeting of lymph. Several spots in

the ileum looked almost gangrenous, and here and there extravasations had taken place. The coats were infiltrated, the mucosa soft, and there were three spots (ulcers) from which the membrane had disappeared.

The stomach, as shown by the specimen, presented a large open cancer, involving the cardiac end, and completely encircling the organ. Several loose sloughs adhered to the surface, but over a great part of its extent the muscle fibres were bare. There was thickening of the peritoneal surface and a few secondary nodules. In looking for the cause of the condition of the bowel, the vessels were carefully examined, and the superior mesenteric artery found to be plugged.

(To be continued.)

NEWS ITEMS.

BALTIMORE.

(*From our Special Correspondent.*)

THE JOHNS HOPKINS MEDICAL SCHOOL.—It is understood that President Gilman will shortly visit Europe in the interest of the Medical School of the University, which the trustees desire to establish as soon as practicable.

THE UNIVERSITY OF MARYLAND.—Prof. W. E. A. Aikin has resigned the Chair of Chemistry in the University of Maryland. Prof. Aikin has filled this position since 1837, a period of forty-six years. He will remain in the faculty as Emeritus Professor of Chemistry. His successor has not yet been appointed.

THE NEW YORK COUNTY MEDICAL SOCIETY AND THE NEW CODE.—The regular stated meeting of the New York County Medical Society was held last Monday evening. Dr. Piffard gave notice that at the next annual meeting of the Society, which occurs in October, he would move the adoption of the following amendment to the by-laws of the Society:

No member of this Society shall assume any sectarian designation indicating that his practice is based on any special doctrine, dogma, or specified method of treatment.

DR. PIFFARD also moved the adoption of the following amendments to the by-laws, which he said he offered in order to keep the Society in harmony, as it was obliged by law to be, with the State Society:

1. The members of this Society shall be governed by the Code of Ethics adopted by the Medical Society of the State of New York February 6, 1882.

2. No person shall be eligible for membership in this Society who is a member of a county society not entitled to representation in the Medical Society of the State of New York.

The amendments were adopted.

MASSACHUSETTS MEDICAL SOCIETY.—The one hundred and second annual meeting of this Society will be held at the Institute of Technology in Boston on June 12th and 13th, under the presidency of Dr. Alfred Hosmer, of Watertown.

The following papers are on the programme:

A Contribution to the Study of the Tubercle Bacillus, by H. C. Ernst, M.D., of Jamaica Plain.

The Use and Abuse of Ergot, by G. L. Woods, M.D., of Springfield; and another paper on the same subject by W. A. Dunn, M.D., of Boston.

Glykogen, by J. W. Warner, M.D., of Boston.

Phlyctenular Disease of the Eyes, by O. F. Wadsworth, M.D., of Boston.

Minor Injuries of the Spinal Cord, by B. H. Hartwell, M.D., of Ayer.

Plumbing Appliances, by T. M. Clark, A.B.

Recent Changes in the Method of Medical Instruction, by E. N. Whittier, M.D., of Boston.

Neurasthenia: its Causes and its Home Treatment, by J. S. Greene, M.D., of Dorchester.

The Artificial Feeding of Infants, by J. W. Spooner, M.D., of Hingham.

The Early Symptoms of General Paralysis of the Insane, by W. B. Goldsmith, M.D., of Danvers.

The Annual Discourse will be delivered on the 13th inst. by Amos H. Johnson, M.D., of Salem.

During the week of the meeting, there will be a sanitary exhibit at the Institute of Technology, illustrating the proper and faulty methods of plumbing, drainage, ventilation, etc.

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending May 19, 1883, indicate that measles has increased, and that erysipelas has decreased in area of prevalence.

Including reports by regular observers and by others, diphtheria was reported present during the week ending May 19, and since, at 17 places; scarlet fever, at 18 places; and measles, at 36 places. One case of smallpox was reported at Detroit, May 19.

OBITUARY RECORD.—The death of DR. MICHEL, Professor of Clinical Surgery, and one of the most distinguished members of the *Faculté* of Nancy, is announced.

—— A cable dispatch from Berne, on May 28, announces the death of the eminent German physiologist, PROFESSOR GABRIEL GUSTAV VALENTIN.

Professor Valentin was born at Breslau, Prussian Silesia, on July 8, 1810, of Jewish parentage. He studied medicine at the Breslau University, taking his degree in 1832. He practised medicine a few years, but in 1836 he became Professor of Physiology at the University of Berne. He published many medical works, and a number of monographs and minor essays.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 21 TO MAY 28, 1883.

CAMPBELL, JOHN, *Lieutenant-Colonel and Surgeon, Medical Director Department of the South.*—Granted leave of absence for one month, on surgeon's certificate of disability.—*Par. 3, S. O. 50, Department of the South, May 21, 1883.*

SPENCER, WM. G., *Captain and Assistant Surgeon.*—Assigned to duty at Fort Hamilton, N. Y. H.—*Par. 2, S. O. 83, Department of the East, May 14, 1883.*

GORGAS, W. C., *First Lieutenant and Assistant Surgeon.*—Granted leave of absence for one month—*Par. 5, S. O. 51, Department of Texas, May 17, 1883.*

HOPKINS, WM. E., *First Lieutenant and Assistant Surgeon.*—Assigned to temporary duty at Whipple Barracks, A. T.—*Par. 2, S. O. 44, Department of Arizona, May 14, 1883.*

MCCREERY, GEORGE, *First Lieutenant and Assistant Surgeon.* To report for duty to the commanding officer of troops in the field near San Bernardino Springs, A. T.—*Par. 1, S. O. 44, Department of Arizona, May 14, 1883.*

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. XLII. SATURDAY, JUNE 9, 1883. NO. 23.

AMERICAN MEDICAL ASSOCIATION.

THIRTY-FOURTH ANNUAL MEETING, CLEVELAND, 1883.

THE PRESIDENT'S ADDRESS.

Delivered June 5, 1883.

BY JOHN L. ATLEE, M.D., LL.D.,
OF LANCASTER, PENNSYLVANIA.

GENTLEMEN OF THE AMERICAN MEDICAL ASSOCIATION: Permit me to express my feelings of gratitude for the unexpected honor conferred upon me at the last meeting of the Association, and to cherish the hope that in fulfilling the duties of this responsible position I may be sustained by your cordial coöperation.

We meet here to engage earnestly in furthering the interests and objects of the medical profession. We have come together from all parts of our broad country, charged with these great responsibilities. It is fitting to express here deep regret at the absence from our councils of delegates from the Medical Society of the State of New York. Let us hope that this absence may be only temporary, and that at the next meeting every State may be represented.

As specialties are so much in favor at the present time, I have thought it well, though far from favoring them on ordinary occasions, to bring prominently forward, in my address to-day, my own rare specialty, namely, the having been a graduate of sixty-three years' standing. Instead, therefore, of calling your attention to the more strictly scientific subjects that are so generally considered upon such an occasion as this, it has occurred to me that some reminiscences of my early medical life might not be wholly unacceptable, or devoid of interest and instruction.

REMINISCENCES OF EARLY MEDICAL LIFE.

When I began my medical studies, in 1815, there were but few medical colleges in the country—the medical department of the University of Pennsylvania, the College of Physicians and Surgeons of New York, and the colleges at Baltimore, Harvard, New Haven, and Lexington, Ky. The University of Pennsylvania was the leading institution, to which students from all parts of the country came. The facilities for clinical instruction at the University were confined to the Pennsylvania Hospital and the Philadelphia Almshouse; but of these lectures and the distinguished clinical teachers I shall speak again.

DR. CASPAR WISTAR.

Having had no opportunities for studying practical anatomy before matriculation at the University of Pennsylvania, I devoted myself more particularly to that branch in my first course of lectures, 1817–18. The chair was then filled by Dr. Caspar Wistar, one of the most able and accomplished teachers of anatomy which this country has produced. His amiable deportment and kind treatment of students made an impression upon me which I shall never forget, and after the lapse of more than sixty-five years the thought of him kindles in my breast emotions of genuine pleasure. As I remember him, he was of medium stature, apparently about sixty years of age, and so impressive was his teaching of anatomy up to the time of his death, which occurred very suddenly, in January, 1818, that his words remain with me yet. He was certainly a man of great personal magnetism, extremely courteous in his manners, and gentle in disposition; he was always ready to converse with the students and help them in their difficulties. It is no wonder that he was greatly beloved by the students. The announcement of his sudden death from disease of the heart, on the night after he delivered his last lecture, produced a shock among the students that I shall never forget.

Just here, I may appropriately allude to the foundation of a social institution, long known in Philadelphia as "the Wistar Parties." Dr. Wistar had been in the habit of inviting to his house, on Saturday evening, men of learning and distinction, both citizens and strangers. The ability and social qualities of the professors of the University of Pennsylvania and of the eminent medical men of Philadelphia, caused always the presence of a large infusion of medical science in the composition of his parties. After his death, these gatherings were revived and continued by his friends, and they were still known as "Wistar-parties" in honor of their founder. In this way originated the celebrated social gatherings, which occupied so important a share in the social annals of Philadelphia. I remember my gratification when young at meeting some distinguished gentlemen from abroad, and many no less distinguished from our own country.

JOHN SYNG DORSEY.

The course of lectures on anatomy, interrupted by the death of Dr. Wistar, was subsequently finished by Dr. John Syng Dorsey, a favorite nephew of Dr. Physick. He completed the course with credit, and was subsequently elected to fill that chair. Unfortunately, he also died after a very short illness, after delivering his introductory lecture, within a week after the beginning of the term. It was a great loss to the University, and a very severe blow to Dr. Physick, one from which he never recovered. At this period there was no American work on anatomy; but about this time Dr. Wistar's *Anatomy* was published, and adopted as a text-book. It was received with great favor, even with enthusiasm, by the students. The assistants to the Professor of Anatomy at this period were Drs. Wm. E. Horner and Hugh L. Hodge, afterwards highly distinguished in their respective branches, anatomy and midwifery.

JOHN REDMOND COXE.

Dr. John Redmond Coxe was the Professor of Chemistry in the winter of 1817–18, a grandson of Dr. John Redman, one of the leading physicians of Philadelphia in his day, and first President of the College of Physicians. Dr. Coxe had the reputation of being one of the most diligent students in Philadelphia. He was very careful in his experiments, and in lecturing was very punctual in filling the whole of the hour allotted to him.

The Chair of Midwifery, during my first course, was filled by Dr. Thomas C. James, a very modest and agreeable gentleman of Quaker origin. He had such a sense of delicacy that he could not bring himself to lecture on the female organs of generation, but entrusted this part of his course to Dr. Horner. Although a graduate of the University of Pennsylvania, he sub-

sequently became a pupil of Dr. Denman, of London, whose work on *Midwifery*, together with that of Burns, and Dr. Dewees' translation of Baudelocque, constituted the principal works on that subject. Dr. James, after Denman, was a strong advocate for the short forceps.

NATHANIEL CHAPMAN.

Dr. Nathaniel Chapman, at this time, and for many years afterwards, filled the Chair of the Institutes and Practice of Medicine. He was a most eloquent and impressive lecturer, and the idol and tried friend and benefactor of the student. He was, moreover, a man of very marked ability, eloquence, and great social qualities. Having to teach the Institutes, as well as the Practice of Medicine, it required two courses of lectures to complete the subject. The physiology of that day was very different from that of the present. The microscope had then hardly begun to be applied to the study of anatomy, and so little did Dr. Chapman appreciate it, that it was a standing joke with him to quote old Leuwenhœck as having discovered with his microscope "twenty thousand devils playing upon the point of a needle," thus foreshadowing some of the most remarkable discoveries of the present day, especially disease germs. Prof. Chapman was thoroughly posted in the departments which he taught, at that time, although they have advanced wonderfully since his day. He was a man of very imposing presence, rather above the medium height, always neat in his dress, perfectly well-bred, and always obliging and polite to the students. I believe that he did more for the advancement of medicine in his day than any other person with whom I was acquainted. He established a school, called Chapman's Institute, for the benefit of his private students, of whom he always had thirty or forty, and other students who chose to attend. The building was in the rear of his house, with a private entrance, and he employed, as teachers of his classes, gentlemen who afterwards became eminent professors at the University and at the Jefferson Medical College, among whom may be mentioned Prof. William P. Dewees, Hugh L. Hodge, and John K. Mitchell.

PHILIP SYNG PHYSICK.

Last but not least among the faculty of that day was Dr. Philip Syng Physick, the great American surgeon, who that winter, 1817–1818, delivered his last course of lectures on surgery. A pupil of John Hunter, he taught the doctrines of that great man. As I recall his course of lectures, it seems to me that he was one of the most impressive teachers that I have ever listened to. Dr. Physick was remarkable for great attention to details, and in his operations upon the cadaver he carefully observed all the rules for operating upon the living body. He also recapitulated the lecture of the preceding day before going on with his subject, by questioning the students who occupied the first two rows of seats in the amphitheatre. I may refer to one incident which may illustrate his method and his carefulness. On one occasion he *stumped* the whole class; he had been lecturing on lithotomy the preceding day, and he put the question to the first student—"What instruments should be provided for the operation?" The answer appeared to have been correctly given, but he was not satisfied. The question was repeated to the next student, and finally to the whole class with the same result. Dr. Physick then said it was "a pin, gentlemen, a pin" that was needed to complete the list. This showed his precision, and impressed upon us the necessity of taking care never to go to an operation without the minutest preparation.

Dr. Physick was a man of medium height, with very regular features. His face at that time was pale, as if he suffered from delicate health. He was of very abstemious habits. I remember on one occasion, at a party given at his house, when the servant brought in a tray with wine, I was standing beside Dr. Chapman, when I placed my hand upon a decanter, as I supposed, of wine; Dr. Chapman touched my elbow and told me not to take that; I filled the glass from another bottle, and afterwards asked the Doctor why he had checked me; he said the first was simply colored water, that Dr. Physick had provided for his own use.

In speaking of Dr. Physick's teaching, I should also say that he always lectured extemporaneously, the didactic lectures on inflammation being read by Dr. Dorsey, his nephew. Dr. Physick was dignified in his deportment, and eminently grave; we rarely saw a smile upon his face. His usual dress in the lecture-room was a blue coat with metal buttons, white vest, and drab pantaloons. He was remarkably staid and reserved in his manner, and was always regarded with reverence and great respect by the students. He never indulged in any flights of imagination, and was purely a practical lecturer who brought his knowledge from the stores of his large personal experience.

One of his favorite precepts, was to insist upon great attention to diet after surgical operations. I may mention this anecdote. In one of his lectures he spoke of a very important surgical operation, and said that there was a necessity for attention to absolute diet. The next day in recapitulating, he asked a student what was meant by absolute diet. The student said "toast or barley water." "Will any gentleman tell me what is meant by absolute diet?" Appealing to the whole class. There was no reply. "Water, gentlemen, water." A precept I have never forgotten, and which, I think, is not sufficiently observed at the present day after important surgical operations.

CLINICAL TEACHING IN PHILADELPHIA.

The clinical teaching of that day was not given at the Medical College, as it now is, but at the Pennsylvania Hospital, and the Philadelphia Almshouse, then in the city; each institution affording an excellent school of instruction to the students. As the clinical hours were the same at both institutions, I chose the almshouse as affording a larger field.

Among the clinical teachers of that day, very few were superior to Dr. Joseph Parrish, who had been a pupil of Dr. Wistar. He was a man of most amiable character, thoroughly devoted to the advancement of the profession; having large classes of private students every year, to whom be lectured, and for whom he also provided able assistants to aid in teaching. One of these was the late Dr. George B. Wood. Dr. Parrish was a man of warm sympathies, and he testified to his benevolence in the manner in which he conducted his clinics. Let me give you an illustration. A poor, weather-beaten sailor was brought to the almshouse suffering very much from rheumatism. Dr. Parrish ordered the man to be clothed in flannel, and have a bottle of porter daily. On the next clinical day, Dr. Parrish, on inquiring, found that neither had been attended to. He repeated the order, with a mild rebuke to the steward. At the next visit, three days afterwards, finding that his previous orders had been disobeyed, he called for the steward and remained at the bedside of the patient until the order was fulfilled.

THE TREATMENT OF THAT DAY.

With regard to the treatment of that day, I shall say little, the text-books then studied fairly present it to you. Would that I could speak more satisfactorily of the treatment of the insane as I remember it. They were generally confined in the basement of the alms-

house in small cells, some with manacles, others with chains, seldom had they access to fresh air, and often they had nothing but loose straw for their bedding. This unhappy and inhuman state of things continued until Pinel and Esquirol established a course of treatment more consistent with the dictates of science and humanity. In a recent visit to the State Lunatic Hospital at Harrisburg, Pennsylvania, of which I am a trustee, not one of the four hundred insane inmates was the subject of mechanical restraint.

At that time, the resident physicians at the Almshouse were not graduates in medicine, but last-course students, who fulfilled their duties while preparing for graduation. The requirements for graduation were attendance upon two full courses of lectures, of four months each, a written thesis on some medical subject, attendance at the Hospital or Almshouse, and an oral examination in the presence of the whole faculty.

THE GREEN-BOX.

Many of the elderly gentlemen present to-day must have heard of the much-dreaded "green-box." During the time of Drs. Rush and Barton, it was reported that favoritism was shown to their respective students, and the same was said of the students of Drs. Chapman and Dorsey. To obviate this, or the appearance of it, a large green screen was placed across one corner of the room, having a door behind it, through which the candidate entered, and here underwent his examination, unknown to any one but the dean of the faculty. This mode of examination was adhered to until after the death of Dr. Dorsey, when it was optional with the student to go into the green-box or present himself openly before the faculty. Some ten or twelve candidates had such a terror of the green-box that they went to New York, where they obtained the degree of M.D. by undergoing an examination and paying the graduating fee.

THE PHILADELPHIA MEDICAL SOCIETY.

Among the facilities for acquiring knowledge offered the students at that time was the privilege of attending the meetings of the Philadelphia Medical Society, which met every Saturday evening. In order to gain admission, as a junior member of the Society, which was composed of honorary and junior members, it was necessary for the student to pass an examination. The committee of the year 1817–18 consisted of Drs. Franklin Bache and Jacob Randolph, the latter being Dr. Physick's son-in-law. I remember with what trepidation I went before the committee, and, to my gratification and surprise, the only question asked me was the composition of Glauber's salts. This examination over, I received a parchment certificate of junior membership, and was admitted to the discussions of the Society. After graduation, I received a certificate of honorary membership. The proceedings of the Society did not differ materially from those of the present day. A paper was read, and subsequently discussed by many of the leading physicians and surgeons of that period, and was a source of great improvement to the junior members.

CALOMEL AND THE LANCET.

It was the time of calomel and the lancet. With regard to the one, I need not speak; but of the latter I feel well assured that the almost total disuse into which it has fallen has cost many valuable lives. From a very large experience in its use, I am satisfied, fully satisfied, that if we depended more on the early use of the lancet in the congestive and inflammatory states of many diseases, our practice would be more successful than it now is. At the present time there is too exclusive reliance upon medicines affecting the nervous and vascular systems, which act with less efficiency, and are less prompt. It is, in my opinion, a very important subject, and I feel assured that ere long the lancet will be more freely used than it is now. In the congestive chills preceding inflammatory diseases, and in the cold stage of intermittents, I have frequently broken up the paroxysm, and relieved the patient by the lancet alone.

In the class of 1817–18, there were many men who afterwards became distinguished in their respective departments. Time will not permit me to enumerate them all.

GEORGE MCCLELLAN.

Among the first was one with whom I was very intimate, Dr. George McClellan. A man of great natural talent, quick perception, and wonderful memory, prompt to decide, and prompt to act, he made himself during his pupilage one of the best anatomists in the country, and subsequently brought more talent into surgery than any man I have ever met with. During his brief, but brilliant career, he performed more surgical operations than any other surgeon in Philadelphia; and he undertook to perform, and did perform successfully, some operations which were considered impracticable by other surgeons. Among these was the removal of the parotid gland. It was my good fortune to visit with him, his first patient the day after the operation; and although it was afterwards reported that it was not the parotid gland, I made a very careful examination of the tumor, and of the patient, and was perfectly satisfied of its identity. This operation he performed several times afterward, one of them on a young Irishman, where Dr. Dease, an eminent surgeon of Dublin, had previously failed.

A beautiful illustration of his diagnostic ability was shown to me when on a visit to Philadelphia; a female infant, about four or five months old, whose parents belonged to one of the most distinguished families in New York, was brought by her father to Philadelphia, to consult the oldest leading surgeons of the city, who all pronounced the case hopeless. The child had from birth, a complete paralysis of the right arm and hand. As Dr. McClellan, at that time, was beginning to acquire popularity as a surgeon, the father was persuaded to consult him. Dr. McClellan made a careful examination, and found that the clavicle was pressing on the brachial plexus of nerves as it passes over the first rib, and that the paralysis was owing to this cause. All that he did was to elevate the shoulder and the clavicle by mechanical means, and the functions of the arm were entirely restored. I saw it playing equally well with either arm on its nurse's lap.

Dr. McClellan was of medium size, fair complexion, and with blue eyes; he was very attractive and agreeable in his manners, very vivacious, and was called "a bundle of nerves." He was very fond of society, and a general favorite wherever he was known. There was no jealousy in his disposition, and I may be permitted to add, that he was the only surgeon in Philadelphia who congratulated me upon the success of my first operation for ovariotomy, in 1843; when I revived the operation, which, after its introduction by Ephraim McDowell, had fallen into disuse, he sought me at my hotel when on a visit to the city, and gave me a most cordial embrace.

Dr. McClellan was among the first to suggest and urge the establishment of another medical college in Philadelphia; and with the assistance of Dr. Eberle, he determined to get a charter from the Legislature. Dr. Eberle being a native of Lancaster county, and having practised both in the city and county for several years before his removal to Philadelphia, had many friends there, and wrote to them asking their as-

sistance in procuring a charter from the Legislature. With the view of furthering the cause, a public dinner was given to Dr. Eberle by the leading gentlemen of Lancaster, and resolutions were then passed instructing our representatives at Harrisburg, to favor the charter. Notwithstanding the opposition that had always existed among the friends of the University to the establishment of another school, a charter was obtained, authorizing the Trustees of the Jefferson College, at Canonsburg, to grant degrees in medicine, and to locate the school in Philadelphia.

JOHN RHEA BARTON.

Another member of the class of 1817–18, a native of Lancaster, and when young a schoolmate of mine, was Dr. John Rhea Barton, who began the study of medicine with my preceptor, Dr. Samuel Humes, and through the influence of his uncle, Prof. Benjamin Smith Barton, of the University, was appointed a resident pupil at the Pennsylvania Hospital. At that time, I believe, the residents were apprenticed for five years. Such was the distinction he obtained in this position that immediately after receiving the degree of Doctor of Medicine, he was elected one of the attending surgeons, an unprecedented event. While in this position he acquired the reputation of being one of the most dexterous operators in the country. A gentleman —a physician—who after graduating here had spent five years in Paris, and who had seen Dupuytren, Boyer, and Desault operate, told me that with the exception of Dr. Physick, who had been his preceptor, he had never seen Dr. Barton equalled as an operator. He was ambidextrous, and instead of changing sides in amputations, he would change hands.

ISAAC HAYS.

Among my fellow-students in 1817–18, and fellow-graduates in 1820, I should be unmindful of what is due to extraordinary merit were I not to speak of one who has done more for American medical journalism than any other physician in the country; I allude to the late Dr. Isaac Hays, the editor of the *American Medical Journal*, by whose labors, professional accomplishments, and excellent judgment, the leading medical journal of this country was established. Having assisted Dr. Chapman in editing *The Philadelphia Journal of the Medical and Physical Sciences*, the motto of which was the ill-natured quotation from Sidney Smith, "Who reads an American book?" Dr. Hays established, in 1827, THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, which to this day, both in this country and in Europe, is admitted to be, in character and ability, the first. Modest and unassuming, he scorned the arts by which many seek prominence, and during a long and very busy life sustained the character of a high-toned and honorable gentleman. To him are we chiefly indebted for the preparation of the Code of Ethics of this Association, which some of our physicians, from motives we cannot appreciate, would be willing to mutilate or destroy.

SAMUEL HENRY DICKSON.

To another fellow-graduate I may with great propriety allude. Dr. S. Henry Dickson was one of the most accomplished scholars, both in medical and miscellaneous literature, it was my good fortune to know. Having obtained, by his extensive acquirements, sound judgment, and high character the first position in his native city, Charleston, South Carolina, he was elected Professor of the Theory and Practice of Medicine in Jefferson Medical College, where he lectured with distinguished ability to the close of his life.

GEORGE B. WOOD.

Dr. George B. Wood, known to many of you, was graduated at the end of my first course, in 1818. The possessor of an ample fortune, he devoted his wealth, his untiring industry, and his great acquirements to the promotion of sound knowledge, and the welfare of the Medical Department of the University of Pennsylvania.

CHANGES IN THE UNIVERSITY FACULTY.

In the winter of 1819–20, when I attended my second course, a change had taken place in four of the chairs at the University. Dr. Physick, in consequence of the death of Dr. Dorsey, had been elected professor of anatomy, and Dr. Gibson was brought from Baltimore to fill the chair of surgery. Dr. Coxe was taken from the chair of chemistry to teach materia medica; and Dr. Robert Hare was appointed to teach chemistry. These changes were not very agreeable to those who, like myself, were attending their last course, as it took from the chair of surgery that great man, Dr. Physick, and placed him in a position where he had to renew his early studies. It placed Dr. Coxe in what might be called his favorite element, for there was hardly a single article of the materia medica, from the time of Hippocrates to that day, that he did not notice in his lectures. It was very amusing to the class, after Dr. Chapman had recommended the use of a medicine as emanating from Dr. Physick, to hear Dr. Coxe, a day or two afterward, taking especial pains to tells us that the remedy had been used from the time of Galen or Celsus. Dr. Hare, who never failed in an experiment before the class, had great hesitation in explaining the rationale, not having the gift of fluent speech. He gave an excellent demonstrative course on chemistry, particularly on the subjects of heat, magnetism, electricity, and galvanism, which, since his day, have excited the attention of the whole scientific world. Dr. Hare was a large man, of great muscular physique, but possessing the manners and feelings of a courteous gentleman.

Dr. Gibson, whom I have referred to as coming from Baltimore, where he had acquired great reputation as a surgeon, had been a pupil of the celebrated Charles Bell, of London. At first, he read his lectures, which made him somewhat unpopular with the class, as his predecessor, Dr. Physick, had always lectured extemporaneously. Being told of this, it was said that he afterwards committed his lectures to memory.

QUIZ CLUBS.

At the time of my attendance upon lectures, there were very few boards of examiners, and the graduating classes were generally divided into "quizzing clubs" of six students, each of whom took notes at the lectures of the different professors. We examined each other twice a week on the lectures of the preceding three days, and recapitulated on Sunday afternoon, having been told by Dr. Wistar that we could not spend Sunday more profitably than in the dissecting-room. So Galen ends his book, *De Usu Partium Corporis Humani*, by saying it is an ἐπωδος, or a song sung standing before the altars of the gods, *hymnis deos celebrantes*. The result of these frequent examinations was that, although we had some idle fellows among us, every member of our club received his diploma.

With the garrulity, and may I not call it the privilege, of your oldest brother, I present you with some of the reminiscences of my college-life. Before I close this address, let me briefly call your attention to some other subjects, which, in my opinion, are of pressing importance. Let me impress upon the mind of every member of the profession the necessity of strict and undivided attention to the duties of his high calling. Let no outside influence operate to interfere with these duties. When you undertake the care of a patient, your whole duty belongs to him. The intermission of

a single visit, which, on your part, may have been devoted to pleasure, may sacrifice the life of your patient.

THE CODE OF ETHICS.

Above all things, ever strive to maintain the honor and dignity of the profession. Let no selfish or mercenary consideration deter you from observing the laws laid down in our noble Code of Medical Ethics. Cultivate friendly relations with your local medical brethren, more particularly the younger; and regulate your intercourse with all men in such a way as to cast no stain upon the honor of the profession, which is in your keeping.

THE PROFESSION BEFORE THE ADOPTION OF THE CODE.

In my day, previous to the establishment of medical societies throughout the country, and the organization of the American Medical Association, and the general adoption of the Code of Ethics, I saw many disastrous effects from the want of brotherly consideration and kindness. The medical men of that day were often in difficulties, patients would be taken from one physician to another without ceremony; and so great was the jealousy existing between them, that for more than twenty years after my graduation, it was impossible to form a medical society in my native city and county, because there were so many aspirants for the honors. Here let me speak of some of the difficulties I had to encounter in my early professional life. Instead of being taken by the hand by the older physicians, every obstacle was thrown in my path—consultations were refused, and the treatment of my patients unfavorably criticised.

WHAT THE CODE HAS ACCOMPLISHED.

By the establishment of medical societies and the adoption of the Code of Ethics, a wonderful change has been effected. We now feel it our duty to sustain our younger brethren, to treat them with courtesy and kindness, to save them from their errors, and encourage them in all their good work. Had the adoption of the Code of Ethics no other result than this, it would have been an invaluable blessing to the profession. But it has accomplished more. It has put the seal of condemnation upon all "isms," and developed an *esprit de corps* that has enlarged the boundaries of our science, and greatly increased the usefulness and social standing of the profession.

Now, gentlemen, before concluding, let me state that, being aware that reports and papers upon every important topic connected with the different departments of medicine will be presented by the Chairmen of the sections, and by individual members, I have not entered upon the discussion of any subject, either medical or surgical.

Our meetings are for the purpose of promoting social intercourse, as well as for the advancement of medical science; but we should devote sufficient time to the discussion of the various subjects presented to us, and not allow them to be too greatly interfered with by social entertainments.

One word more, and I have done, and I say it chiefly as a word of encouragement to the younger among you. At the close of a long life, one devoted unreservedly to the study and practice of medicine, I will say that, notwithstanding its uncertainties, its fatigues, its anxieties, its bitter disappointments, I am completely satisfied that in no other career can a man more fully accomplish his whole duty to God and to his fellowmen; so that when life here is ended, it can be truly said of him as—be it said with all reverence—was said of Him whom we all should imitate, *pertransivit benefaciendo—He went about doing good*. Trusting that our proceedings may be both harmonious and profitable to us all; and thanking you again for the honor you have conferred upon me, I sincerely hope that the recollections we shall carry home with us will be both agreeable and lasting.

ORIGINAL ARTICLES.

VALUE OF EARLY OPERATIONS IN MORBID GROWTHS.

BY S. D. GROSS, M.D., D.C.L. OXON., LL.D. CANTAB.

(*Read before the American Surgical Association, May 31, 1883.*)

THE value of early surgical interference in morbid growths, especially the malignant, has long been recognized by writers and teachers, but, unless I greatly err, it has not been discussed with that degree of force and emphasis to which its intrinsic merits entitle it. I therefore purpose laying the matter before you, if possible, in a stronger, if not also in a clearer light, than any in which it has hitherto been presented, and in this wise bring it more fully under your notice for elaborate and dispassionate consideration.

The great reasons for the removal of tumors in the early stages of their development, may be thus stated: 1. The less risk of shock and of hemorrhage; 2. The more effectual riddance of the diseased structures; The diminished probability of septicæmia, or blood-poisoning; 4. The avoidance of unsightly scars; and 5. The less risk of a recurrence of the morbid action, either at the seat of the operation or in other parts of the body. These propositions are so self-evident that any formal discussion of them seems to be out of place; nevertheless, it may be well to call special attention to a few points in order to impress them more fully upon your mind.

The fact is now generally, if not universally admitted, that all morbid growths or tumors, whether benign or malignant, are of local origin. That the constitution, in certain conditions, as when from any cause the general health is more or less seriously impaired, may predispose to such formations, is not improbable, but that a neoplasm can be developed in any organ or structure of the body of a perfectly sound person, without some local cause, is what no enlightened pathologist of the present day believes or teaches. There is unquestionably occasionally a hereditary tendency to the development of morbid growths, both benign and malignant. We see this tendency, sometimes in a remarkable degree, displayed in warts and sebaceous cysts. Examples of the latter I have repeatedly witnessed in three generations, and instances doubtless occur in which this disposition manifests itself still further. Malignant diseases, as carcinoma and certain forms of sarcoma, occasionally betray a similar tendency. As many as three, four, or even five cases of scirrhus of the mammary gland have been noticed in as many different members of the same family. Epithelioma of the lip, skin, vagina, and uterus occasionally exhibits a similar freak.

I state, as another incontrovertible proposition, that all morbid growths, tumors, or neoplasms are the product of perverted nutrition, in which the comparatively few cells native to the part are re-

placed by colonies of young cells, of the latter of which the new product is essentially composed.

All morbid growths are developed, directly or indirectly, under the influence of inflammatory action, the result of external injury, or, as is more frequently the case, of some mechanical obstruction, causing, in the first instance, congestion of the part, and this, in turn, incited action and inflammation, both leading sooner or later to abnormal cell-growth, cell-formation, or cell-development. It is in this way, and in this way alone, that we can satisfactorily explain those morbid growths, both benign and malignant, which, as the phrase goes, arise without any assignable cause. One of the most simple of all tumors, the sebaceous, is formed under the irritating influence of its own natural secretion, retained by the closure of its natural outlet. Obstruction of a lacteal duct is, there is no doubt, a frequent starting-point of scirrhus of the mammary gland. There is not a surgeon of any experience anywhere who has not occasionally met with cases of carcinoma which were due, directly or indirectly, to the effects of local injury.

Having laid down these propositions as so many fundamental principles, we are now in a position to take up the question of the importance of early surgical interference in morbid growths. The remarks which I shall offer under this head are intended to apply more especially to malignant neoplasms.

There are some tumors whose distinguishing features are so well marked, even in their earlier stages, that he who runs may read. On the other hand, great difficulty often presents itself, sufficient to perplex and puzzle the wisest and most experienced head, as well as the most cautious observer. When the tumor is fully developed, when its features stand out, as it were, in full relief, there can rarely be any doubt about its true nature, certainly seldom in the mind of an educated surgeon. Unfortunately few of the cases of malignant disease, either in our rural districts or even in our larger towns, come under our observation in time for early surgical interference. In the great majority of instances the mischief, in the form of great structural lesion, if not serious constitutional involvement, is unfortunately effected before the scientific and enlightened practitioner has an opportunity of inspecting the morbid product. Three circumstances may be enumerated as contributing mainly to this result: the want of correct diagnosis, the dishonesty or knavery of the professional attendant, and the folly or stupidity of the patient.

It is in vain to conceal from ourselves the fact that there are comparatively few reliable, ready, or trustworthy diagnosticians. Diagnosis is a high art, and it is not saying too much that the profession, as a body, are not sufficiently familiar with it to render it at all times, or even in a minority of cases, properly available at the bedside. It is, of all the arts in our profession, the one which demands the greatest amount of refined culture, experience, and tact, not culture, experience, and tact of an ordinary type, but of the highest possible type. Founded essentially upon a thorough knowledge of pathological anatomy, a branch of science little cultivated in any of our schools, and totally neglected in most, it is not surprising that the art of diagnosis should be so little understood by the generality of practitioners, and so many errors committed in the examination of morbid growths. If there is any one thing in the organization of our medical colleges more culpable, I had almost said more criminal, than any other, it is the exclusion from their curriculums of the study of pathological anatomy. Just in proportion as our knowledge of morbid structure is positive, accurate, and comprehensive will be the probability that we shall become skilled diagnosticians, and conversely. Hence, so long as this state of things exists, we shall look in vain for any marked improvement in this direction, and what is true in this respect is true alike of city and country practitioners, standing, as they do, upon the same unfortunate platform.

Knavery, dishonesty, and self-conceit are found in all ranks of life, and among all classes of men. That our profession should be wholly exempt from these infirmities is not to be expected. It abounds in charlatanry, in men who promulgate their claims in all kind of ways to allure and deceive the people by holding out false pretensions of cures, which they well know can never be realized. In this manner important time is often lost by permitting the case to progress until the propitious period for affording relief has passed by. In making these remarks, I desire to apply to the term "charlatan" a wider signification than the one in which it is usually employed. There are "quacks" in every profession, the clerical and the legal not less than in the medical; men who do not hesitate to prostitute their honor to self-interest, and make the merest trade of their vocation. Money is their god, and they worship him in any way best adapted to their object. Such men are not any better than the avowed, advertising charlatan.

A patient laboring under a serious morbid growth may consider himself as peculiarly fortunate if, in the early stage of his troubles, he fall into the hands of an intelligent, upright, conscientious surgeon. Such a man will not hesitate to express his honest convictions. He will not esteem it a disgrace to say to his patient, "your case is one I do not comprehend; it is an uncommon case; it is beyond the grasp of my limited experience; go and consult some one whose opportunities of observation have been more extensive; and be sure to lose no time in carrying my advice into effect. The knave, on the other hand, will do all he can to mislead his patient, and lull his fears by assuring him that his disease is of no importance, or by telling him that it will either remain stationary or, in time, disappear spontaneously. He is afraid to tell the truth, lest by showing his ignorance he should lose prestige, and thus damage his practice. To cap the climax of his impudence, he may even assure his patient that he is fully master of the situation, and that he knows as much about the nature of the case as the wisest and most experienced surgeon in the land. Now, it is precisely men of this stamp, and their name is legion, that do the mischief.

Ignorant of the art of diagnosis, or incapable of telling the truth, they allow the case to proceed from bad to worse, until the poor patient, in a fit of desperation, seeks, as a *dernier resort*, relief at a more enlightened and more honest shrine. The examination now made reveals the fact that the disease has made hopeless progress, and that any operation, if proper at all, can afford only temporary relief. Let me instance, as an illustration of my meaning, carcinoma of the female breast.

This disease, as is so well known, generally begins in the substance of the mamma as a small nodule or tumor, hard on pressure, and the seat of occasional pain of a shooting or darting nature. The woman is forty-five years of age. As the morbid action advances, the growth enlarges, the pain increases in severity and constancy, and, by and by, retraction of the nipple is noticed. Gradually the growth becomes more and more fixed in its situation, and if now the glands in the axilla—naturally so diminutive as to be scarcely distinguishable—be examined, they will be found more or less enlarged and indurated. The diagnosis is not difficult. The case is one of scirrhus, nothing else. A careful examination of the breast, and a careful consideration of the history of the case, leave no doubt as to its true character. If the patient is under forty years of age, or from twenty-five to forty, with a hard, movable nodule, the seat of occasional darting pain, especially annoying during the menstrual period, unaccompanied by change in the nipple, in the surface of the breast, and in the axillary glands, we assume that the neoplasm is a fibroma or adenoma, and unhesitatingly assure the patient that excision of the growth will eventuate in a complete cure.

In carcinoma of the breast, the honest and enlightened surgeon does not wait for involvement of the axillary glands or serious structural disease. He knows that the patient's safety, present and prospective, lies in the early use of the knife and in thorough excision. He urges the importance of prompt interference, and assures the patient that, if the operation be properly done, it will probably eventuate in a permanent cure, or, if relapse occur, that there will be a comparatively long exemption from suffering. Everbody knows what the result of excision of the mammary gland in ordinary cases of cancer is; how rarely the disease is completely removed, and how few women live beyond eight, ten, or twelve months after such interference. In all such cases, cancer cells have invaded the neighboring structures beyond the reach of the knife, especially as ordinarily employed, and serve as foci of new neoplasms. It makes one's very soul ache to see so many women doomed to endure the most frightful suffering in carcinoma of the breast for the want of a correct early diagnosis and the thorough ablation of the diseased structures. Of all the agony I have ever witnessed, there is none at all comparable to that arising from this form of malignant disease of the mammary gland in its more advanced stages.

Finally, there is a class of patients, the subjects of neoplasms, who, influenced by timidity or mock modesty, wilfully deceive themselves. Such persons are fully aware that there is some disease going on somewhere—that there is a thief concealed in some part of the house—but they are afraid to have the matter properly investigated, lest their worst fears should be realized, and be thus made miserable. They conceal from themselves, as well as from their friends, their true condition, and when this condition is at length discovered, it is generally found to be too late to afford any benefit, except of the most transient kind, by surgical interference. Like the ostrich, they hide their heads under their wings in the delusive hope of thus escaping the danger which threatens them. Of such cases, I have seen not a few in the course of my practice.

What has now been said is true alike of carcinoma, of sarcoma, and even of benign growths. In carcinoma, the cells are conveyed from the original disease by the lymphatic vessels, and in sarcoma by the bloodvessels, whereas in the ordinary tumor the increase is due simply to cell-proliferation, which often proceeds with extraordinary rapidity, the growth in a short time acquiring an enormous bulk.

In all operations undertaken for the removal of neoplasms of whatever nature, the golden rule is to perform the work as thoroughly as possible. If this cannot be done it is better in many cases, if indeed not in all, not to meddle with the growth at all, as such interference often only tends to light up increased activity, not only in the abnormal structures themselves, but in the surrounding ones. In carcinoma, the knife, as already repeatedly stated, cannot be employed too early. The longer it is withheld the greater will be the probability, not of relapse, properly so called, but of some of the cancer cells being left behind, buried out of sight, and thus serving as new centres of morbid action. All secondary developments, as enlarged and indurated lymphatic glands, should of course be removed in immediate succession. All sarcomatous neoplasms are, as a rule, dangerous formations, however early subjected to the knife, not so much on account of any inherent tendency to recurrence after extirpation, as from their liability to attack other parts of the body from causes similar to those which gave rise to the primary disease. The worst of all the sarcomas is the round-celled. Any rapidly growing tumor is, as a law, a bad subject for successful surgical interference. In excising the mammary gland for the removal of carcinoma, the plan so successfully adopted of late years by Dr. S W. Gross, of cutting widely around the diseased structures, and healing the wound by the granulating process, is worthy of all praise. In a number of cases thus treated by him, the result has been eminently gratifying, one of the patients remaining perfectly well after the lapse of nearly five years from the time of the operation.

All benign growths of rapid development cannot be extirpated too soon. Let us, for example, take a cystic tumor of the ovary. No one will deny that a neoplasm of this kind of small bulk can be removed more easily, and with less risk to life, than a large one, or one of long standing. In the former case, there will probably be no adhesions, and little

or no danger of hemorrhage or shock; a comparatively small incision will be required to expose the mass, and the resulting peritonitis will be restricted within the healthy limits, the limits of repair. In ovarian cysts of large size, the reverse of all this is usually the case; there is also apt to be greater shock and greater liability to blood-poisoning. Similar remarks are applicable to chondromas, fibromas, and osteomas; operated upon early in their progress, their removal is generally easily effected with little or no risk to life; allowed to remain until they have attained a large bulk, the troubles and dangers of operative interference are augmented a hundred-fold. Nothing more happily illustrates the truth of the old adage, "A stitch in time saves nine," than early operations for the cure of such growths.

What should be the rule of action of the surgeon in cases in which, as for instance, in carcinoma of the breast, in which, perhaps, several operations have already been performed, there is a large ulcerated surface, attended with excessive pain and a large quantity of the foulest discharge, poisoning the very atmosphere which the sufferer is obliged every moment to inhale? Surely no sensible and humane practitioner would hesitate in such a condition to do the only rational thing to be done—to sweep away the whole mass of disease, so far as it is accessible to the knife, and then treat the wound and the system upon general principles. Such a procedure is the only feasible one of relieving pain, of moderating suppuration, and of making the patient temporarily comparatively comfortable. Death under such circumstances is generally hailed as a welcome visitor. In malignant disease of an extremity, attended by such a state of things, the proper remedy would, of course, be amputation without any ulterior hope of a cure. In the throat, portions of the sprouting mass may be clipped off with the scissors, and in the nose and the vagina, scraped away with special instruments. When all hope is at an end, the only thing to be done is to impart a silver lining to the remnant of life by means of anodynes, administered in quantities sufficient to relieve pain and promote sleep.

What I have here said respecting early surgical interference in malignant and other morbid growths applies with equal force to many other surgical affections, as well as to diseases in general. Thus an abscess, if not opened early and freely, is sure to cause serious destruction of tissue, to say nothing of the concomitant pain and other distress. A small stone is more easily crushed or extracted than a large one, while the risk to life is incomparably less, inasmuch as there is less danger from shock and hemorrhage, laceration of structure, urinary infiltration, pelvic cellulitis, peritonitis, pyæmia or uræmic poisoning. Besides, the longer a stone remains in the bladder and the more it increases in size, the greater will be the chance of its causing serious disease of the bladder and of its dependencies.

A pneumonia in its incipiency is, in general, easily managed. Rest in bed, abstinence from food and excitement, and an anodyne diaphoretic, with a turpentine stupe or a dozen dry cups to the chest, usually suffice to cut short the attack in a few hours, or, at most, in a few days. Allowed to progress, it becomes one of the most formidable maladies with which the physician has to cope, and forms one of the great sources of mortality, especially of advanced life.

A CASE OF NEPHRECTOMY FOR MEDULLARY CARCINOMA, AND PARTIAL CHOLEO-CYSTECTOMY FOR CALCULUS, IN THE SAME SUBJECT.

BY SAMUEL W. GROSS, M.D.,
PROFESSOR OF THE PRINCIPLES OF SURGERY AND CLINICAL SURGERY IN THE JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA.

(*Read before the American Surgical Association, June 1, 1883.*)

ON the 14th of April, 1883, I was requested by Dr. William V. Keating to see with him a widow, fifty-nine years of age, who first noticed a small and painless tumor in the right iliac fossa, three months previously. The tumor occupied the lower right lumbar and inguinal regions and about one-third of the hypogastric region, was apparently as large as a child's head, nodulated, of tolerably firm but unequal consistence, mobile, everywhere dull on percussion, there being not the slightest evidence of the presence of the intestines in front of it, and a few drops of bloody fluid were obtained with the exploring needle.

Dr. Keating informed me that the patient had an attack of hæmaturia towards the end of February, which was repeated twice in March, the last requiring the internal administration of ergot for its control. About the middle of February, she began to have pain in the loins, and especially in the right one, which increased in severity with the growth of the tumor. From an examination made two weeks before I saw her, Dr. Keating excluded disease of the uterus or ovary, and diagnosticated carcinoma of the kidney. With the exception of a somewhat sallow and worn appearance, and attacks of migraine, the patient was in her usual good health.

The existence of a rapidly growing tumor and hæmaturia certainly pointed to malignant disease of the kidney; but the mobility of the mass, the fact that it was first observed in the anterior and lower portion of the belly, and that a lateral origin could not be traced, along with the absence of some portion of the intestines in front of it, rather favored the idea of sarcoma or carcinoma of the ovary. In his recent work on *Ovarian and Uterine Tumors*, Mr. Wells states that neoplasms of the kidney are fixed, that they are situated behind the intestines, and that they are originally detected between the false ribs and the ilium, whence they extend first towards the umbilicus, next into the hypogastrium, and lastly downwards towards the groin. As these symptoms were reversed in the case under consideration, it is quite evident that, however reliable they may be when the growth is small, they cannot be depended upon when the growth is large. The diagnosis was also obscured by the condition of the bladder, the fundus of which was found to be tender on exploration with the sound, so that it might have been a possible

source of the hemorrhage, particularly as the urine contained no other foreign elements than blood-corpuscles.

Under these circumstances, it was determined to advise the patient to submit to an exploratory incision, with the understanding that the question of further interference be left to our judgment.

With the assistance of Dr. Keating, Dr. Mears, Dr. Hearn, Dr. Wirgman, and Dr. Newman, the operation was performed, under ether, and with strict antiseptic precautions, on the 20th of April. An incision was made from two inches below the umbilicus along the linea alba for three inches, and hemorrhage arrested with artery clamps, before the peritoneal cavity was opened. Exploration of the tumor showing that the kidney was the organ involved, the incision was prolonged to within two inches of the tip of the ensiform cartilage, when the enormously enlarged and fatty right lobe of the liver was seen to extend into the upper right lumbar and umbilical regions, the gall-bladder, distended with bile, and occupied by a stone as large as a Spanish olive, reaching almost to the umbilicus. The peritoneum covering the anterior surface of the tumor was pervaded by large vessels. This was divided to a slight extent, and rapidly peeled off with the fingers, the procedure being attended with considerable venous hemorrhage. On account of the friability of the tumor, and the projection of a fungous mass along the side of the pelvis of the kidney, it was thought best not to incur the risks of hemorrhage by endeavoring to ligate the ureter and renal vessels separately. Hence the pedicle was transfixed, and tied in two portions with stout carbolized pure silk threads, and the tumor severed from its attachments. Furious bleeding occurred from the renal artery; but Dr. Mears succeeded in grasping the pedicle with his fingers, when I was enabled to encircle it with a catgut ligature, through which further loss of blood was effectually prevented. At this stage of the procedure, the color had left the face, and the pulse was very feeble. The calculus was then drawn down into the fundus of the gall-bladder, both of which were cut away after the latter had been secured with a catgut ligature. The peritoneal cavity having been carefully cleansed of blood, the edges of the incision were united with silver sutures carried through the entire thickness of the abdominal wall; a drainage-tube was inserted in the lower angle of the wound, and carbolized gauze was secured in position with a flannel bandage. The operation occupied fifty-five minutes, and, towards its completion, brandy and iced water were freely administered by the mouth, with the effect of steadying the pulse and relieving the pallor.

The patient reacted well, and at 4 P. M., or three hours after the operation, a hypodermic injection of morphia and atropia was administered on account of suffering. At 8 P. M. the pulse was 108, and the temperature, taken by the mouth, was 100.1°. The catheter drew off three ounces of urine.

April 21. — The patient passed a comfortable night, until 4.30 A. M., when she complained of slight nausea and pain. Brandy and iced milk have been administered every three hours. The urine was drawn off at 6 A. M. Morning temperature 99.4°, and pulse 100. The bladder was evacuated at 9.30 A. M., and again at 2.30 P. M., and a subcutaneous injection of morphia given at the latter hour, which was repeated in three hours. Evening temperature 100.1°; pulse 104. Urine drawn off at 8.30 P. M.

22d.—At 11 P. M. last night the patient was seized with a slight chill, and vomited a small quantity of bile. The temperature was 98.4°, and the pulse 130, which had risen respectively to 103° and 148 at 12.30 A. M. At 1 A. M. half an ounce of urine was evacuated; an hour later, she had quiet delirium; and at 3 A. M. she had another hypodermic injection of morphia to relieve her great pain and restlessness. At 6 A. M. the catheter failed to bring away any fluid, and from this time until her death, twenty-three hours later, there was complete suppression of urine, for which infusion of digitalis and hot applications to the left lumbar region were ordered. At 8 A. M. the pulse was 132, and the temperature 102°. On dressing the wound, the parts were found to be perfectly dry, and as there had been no escape of fluid through the drainage-tube, the latter was removed. There was some tenderness in the right loin and slight tympanites in the left lumbar region. Dressings reapplied. 11.30 A. M., pulse 138, and feeble. 6 P. M., pulse the same; temperature 97°; hands cold; intellect clear; voice strong; tongue moist. Morphia administered by the skin. 10 P. M., pulse flickering and scarcely perceptible.

23d.—At 1 A. M. patient became unconscious, and was very restless, and death ensued at 5 A. M., or sixty-five hours after the operation.

On post-mortem inspection, the wound was found to have united throughout the greater portion of its extent. The peritoneal cavity contained about six ounces of blood-stained serum, and some of the coils of the small intestines were livid, and slightly adherent to one another. The left kidney was apparently sound and slightly congested. The bladder was empty and contracted; the liver was greatly enlarged and fatty. The stumps of the pedicle of the kidney and of the gall-bladder were in an excellent condition. The viscera and lymphatic glands were free from secondary growths.

The kidney weighed eighteen ounces, and measured fifteen inches and a half in its long circumference, and ten inches and a quarter in its short circumference. With the exception of one inch of its upper extremity, it was converted into a medullary tumor which, on subsequent minute examination, proved to be carcinomatous.

The fatal issue was evidently due to peritonitis, complicated by suppression of urine, which was not secreted for twenty-eight hours before death. Indeed the total amount drawn off during the first thirty-seven hours scarcely amounted to sixteen ounces, and it was for this reason that we were somewhat chary in administering opium. In the way of nourishment, she took milk, brandy, and champagne, all of which were well borne by the stomach.

The kidney has been extirpated for sarcoma and carcinoma twenty-two times, the operators having been Czerny in five cases, Kocher in two cases, and Wolcott, Martin, Langenbuch, Jessop, Hueter, Lossen, Barker, Byford, Bardenheuer, Whitehead, Hicquet, Luecke, Adams, Thornton, and myself, respectively, in one case. The nature of the tumor is recorded as sarcoma of the kidney in 14; carcinoma of the kidney in 3; encephaloid of the kidney in 3; sarcoma of the capsule of the kidney in 1; and perinephritic sarcoma in 1. Of the 22 cases, 1 was under treatment at the date of the report, 9 recovered, and 12, or 57.14 per cent., died. Fifteen of the operations were by the abdominal incision, of which 5 recovered, and 10 died; and 7 were examples of the lumbar incision, of which 4 recovered, 2 died, and 1 was still under treatment. The causes of death were primary hemorrhage in 2; collapse ten hours after furious bleeding in 1; peritonitis in 3; septic peritonitis in 1; and shock, pulmonary embolism, uræmia, septicæmia, and exhaustion from profuse purulent discharge each in 1.

It will thus be seen that, apart from the risks common to all ventral and lumbar incisions, the great danger is from hemorrhage, which, even if it does not terminate fatally, may be expected to be considerable in the majority of cases, from the renal artery, the renal vein, particularly on the right side, or from one of the large veins ramifying over the tumor. Hueter's patient perished during the operation from laceration of the renal vessels. In one of his cases, in attempting to enucleate the tumor, Czerny tore the renal artery, and was obliged to tie the aorta, the patient surviving ten hours; and in a second case the patient died on the table from bleeding from the lacerated renal vein. Luecke tore the vena cava, but arrested the hemorrhage by temporary compression, the patient expiring from uræmia on the fourth day, the remaining kidney being cystic and contracted.

In expressing an opinion as to the wisdom of extirpating a kidney the seat of malignant disease, the questions of the immediate mortality of the operation, of the chances of early recurrence, of the prolongation of life, and of a final cure must be considered.

1. As I have pointed out, the mortality of the procedure is 57.14 per cent., which is not only greater by 20 per cent. than that after nephrectomy for other lesions, but also exceeds that of colectomy, laryngectomy, or any other excision for malignant growths, with the exception of resection of the pylorus and abdominal hysterectomy. On this ground, therefore, the operation is to be condemned.

2. The question of recurrence is not easy of solution, since of the nine recoveries, there is no further history in two; one died of recurrence in nine months, the case having been that of a child two years and a half old, under the care of Jessop; one died of secondary growths in forty-five days, the primary growth having existed two years; and five remained well, respectively, for thirty months, twenty-two months, three months, two months, and forty-six days. Hence, the disease returned in 28.57 per cent. of the cases. All of the tumors were sarcomatous. Of the patients who did not survive the operation, in at least four—the growths having been sarcomatous in two and carcinomatous in two—portions of the tumor were left behind, and continuous recurrence would, of necessity, have carried them off. Of the nineteen living or dead cases in which the result is known, therefore, the disease returned or would have returned in six, or 31.57 per cent.

3. Extirpation of the kidney for malignant growths certainly does not prolong life, if the statements of Rohrer and Roberts be true, that the average duration of life without operation is two years and a half for adults, since, of the cases in which this point could be traced, the average life was rather less than twenty-four months.

4. The cases are too few upon which to base the decison of final cure; but the record of two patients who remain well for thirty months and twenty-two months is far from being a gloomy one, in an affection which is invariably fatal if not subjected to surgical interference.

Although the immediate mortality is so great, and although the recurrences number nearly one-third, I am of the opinion that, after the risks have been fully explained to him, the patient should be given the chance if he desires it; and this view is strengthened by the fact that primary malignant disease of the kidney evinces less tendency to invade the surrounding tissues, and give rise to metastases, than similar disease in other organs. Kühn declares that secondary growths are found in only 28 per cent. of the cases in children, and in 44 per cent. in adults. If these statements be true, nephrectomy, in the early stage of the affection, should in the future show more favorable results than have attended it up to the present time, especially as the majority of the growths of the kidney are of a sarcomatous nature.

In the extirpation of sarcomatous or carcinomatous kidneys, the following rules should, if possible, be rigidly adhered to: The capsule of the organ should always be removed; the incision, when the growth is large, should be made along the outer side of the rectus muscle, as recommended by Langenbuch, through which the ureter and renal vessels can be more readily and safely reached than through the median ventral incision; and the ureter should be pinned outside the abdominal incision, as practised by J. Knowsley Thornton, so that the septic material which it contains may not be left in the cavity of the belly. Another real source of danger is sloughing of the ligated ureter when dropped into the abdomen. Such an accident happened to Mr. Thornton, in his case of extirpation of a kidney for sarcoma of its capsule; but, as he informed me in a letter dated April 1, 1883, the slough came away through the drainage opening on the fortieth day, and his patient was alive at the time that he wrote me.

The gall-stone was removed with the investing portion of the gall-bladder to get rid of a source of discomfort in the event of the patient's recovery.

That the operation would not increase the risks was inferred from the fact that Langenbuch, in 1882, successfully extirpated the gall-bladder of a man, forty-three years of age, on account of calculous concretions. The stone might have been removed by an incision, which could have readily been united with the continued suture; but the former course was deemed the more advisable, as the weak condition of the patient demanded the immediate closure of the abdominal incision in order that she might be put to bed, and that bottles of hot water might be applied to the extremities.

MEDICAL PROGRESS.

Quebracho in Dyspnœa.—Mariani thus sums up a paper on quebracho in the treatment of dyspnœa: 1. Quebracho diminishes the frequency of the respirations and cardiac contractions. 2. Its action appears to be principally directed on the heart, strengthening and regulating its contractions, either directly or by the influence of the nervous system. 3. This action is evident and immediate. 4. It is the only remedy which has a manifest antidyspnœic action. 5. In nervous dyspnœa it must be tried in a greater number of cases to judge of its action. 6. It probably produces the same effect in dyspnœa from acute affections of the thoracic organs. 7. The prolonged administration produces no alteration in other organs or functions.—*London Med. Record*, May, 1883.

Peritoneal Transfusion from an Artery.—Drs. Corona and Cocco-Pisani, after making experiments on animals as to the effects of direct transfusion from an artery into the peritoneal cavity, report the following results: 1. Pure blood, passed directly from a carotid artery into the perineum of another animal, is entirely absorbed. 2. In small animals, three ounces of blood had been entirely absorbed in five days. 3. The blood, until its disappearance, remains fluid in the peritoneal cavity. 4. The increase of hæmoglobin begins after twenty-four hours, and continues for a certain indefinite time. 5. The animal suffers no injury on the part of the peritoneum or of any other organ.—*Centralblatt für Chirurgie*, March 24, 1883.

Rupture of the Sciatic Nerve.—Dr. Conrad Küster reports a case in which a rupture of the sciatic nerve was mistaken for fracture of the neck of the femur. The patient, a strong man, æt. 30, slipped and fell backward while walking. He immediately felt a severe pain in the right leg, and numbness in the foot. He was unable to stand, and was carried to his house, where Küster saw him on the following day. At that time, he was suffering great pain in the limb—so great that a dose of morphine only partially relieved it. The limb was rotated outward, and seemed shortened. There was slight swelling in the neighborhood of the hip-joint, and pain on pressure was most severe at this point. At first sight, there seemed to be a fracture of the neck of the femur. This diagnosis had been guardedly made by two physicians, who saw the case soon after the accident, but, on account of the intense pain, had not made an examination. Dr. Küster diagnosticated rupture of the sciatic nerve, as there was no crepitation, and passive movements caused but little pain. The subsequent conduct of the case confirmed this diagnosis. Morphine was given to relieve the pain, and warm baths administered as soon as possible. The patient was in bed over six weeks, and five months afterwards was able to go about with a crutch and stick.—*Berliner klin. Woch.*, March 26, 1883.

Refracture of the Patella.—Mr. H. Parson gives the particulars of a case of refracture of the patella (for the third time), with a description and illustration of a new appliance for treating fractured patella. It consists of two semilunar pieces made of some round, narrow, unyielding material, shaped to fit the edges of the lower and upper fragments. One piece slides on the other and admits of closing and separating them by means of screws and without any other movement; so that, when adjusted and firmly strapped to the side supports of a suitable splint prepared for it, the upper and lower pieces are perfectly rigid one with the other. It is then almost impossible for the patella to slip out of position. The semilunar pieces being narrow, they form grooves for themselves behind the fragments, and have a tendency to run under the bone instead of over-riding as most other appliances do; thus the pieces are kept firmly in good position in their proper plane and have no tendency to tilt. This apparatus was applied about the end of the third week from the date of the accident, and the patient removed to the couch. At the end of the fourth week he came down stairs with assistance, and went out in a Bath chair. At the fifth week he walked round the garden with the aid of sticks. At the seventh week he walked a mile with one stick. At the end of the eighth week he returned to business, walking to and fro, that is, two miles daily. He could walk well wearing the appliance, and experienced very little inconvenience, and to the best of my knowledge, the fragments never slipped once during the twenty weeks that he wore the splint. The pressure was relieved at times by small tufts of cotton-wool, and by wearing an old splint at night, but during the latter part of the time nothing was worn at night, thus abrasions from continued pressure were avoided entirely.

The patient now walks well, and is not particular as to distance, but still wears a contrivance to support the knee-cap and limit the movements of the joint. The advantages claimed for the appliance are these:

1. As soon as the primary inflammation has subsided and the apparatus firmly and properly adjusted, the patient can begin to move about, and in a short time follow his usual business pursuits.

2. The long confinement to bed is avoided; thus the patient retains his health and strength, and the condition is more favorable to the repair of tissues.

3. Easy adjustment of fragments and the keeping of them in good position, without fear of slipping when the patient is walking.

4. The slight movement of knee in walking prevents a stiff joint, and keeps up sufficient activity in the parts to complete the union.—*The Lancet*, May 19, 1883.

Wood-wool, a New Surgical Dressing.—For the past six months Prof. Paul Bruns, of Tübingen, has been using a new material as a surgical dressing, which he calls "wood-wool," which is better and cheaper than gauze or wadding, and fully equal to oakum, tow, or turf. It is prepared antiseptically, in the same manner as the other dressings, though he prefers the sublimate wood-wool. After the wool is prepared and dried, it is impregnated with a one-half per cent. corrosive sublimate solution and ten per cent. of glycerine. Its capacity for absorbing is superior to that of any other dressing. After an operation, the wound is washed with the sublimate solution, one per cent.; then drainage-tubes are put in place, and the dressing completed by the application of wood-wool, covered with sublimate-disinfected gauze. Prof. Bruns has used this dressing in over one hundred operations, and is highly pleased with the results.—*Berliner klin. Wochensch.*, May 14, 1883.

Insufflation and Swallowing Shot in Ileus.—Pedrini has treated three cases of ileus, with well-marked symptoms of invagination of the bowels, obstinate constipation, stercoraceous vomiting, pain, etc., by making the patient swallow, after all other remedies had failed to give relief, five or six bullets, and five pounds of No. 3 shot; at the same time using prolonged and repeated insufflation of air by the rectum. The success in each case was complete, relief being quickly obtained, and the patient making a good recovery.—*London Medical Record*, May, 1883.

Relation of Liver Abscess to Dysentery.—Sir Joseph Fayrer thus summarizes the relation between abscess of the liver and dysentery:

1. The so-called abscesses which originate in local deaths of parenchyma (pyæmia, embolic deposits, or infarcts) are cavities varying in size from a mere speck to an orange, containing débris, sanies, puriform matter, leucocytes, and finally pus. They are seen in various stages of development, and are not necessarily confined to the liver, but occur in other viscera or regions of the body. These are truly pyæmic.

2. There is, I believe, a form of liver abscess coexistent with, and perhaps due to dysentery, which is the result of direct absorption and transference of pus or septic matter from the bowel to the liver through the mesenteric veins. Such may be solitary, double, or triple. This is also a very dangerous form of the disease, though not necessarily fatal, as it is feared must always be the case in the former variety.

3. Dysentery, malarial fever, and hepatitis may coexist, or supervene on each other as effects of common climatic cause; it seems natural to ascribe the liver abscess in such cases to the dysentery, but it is probable that they are rather coincidences than consequences of each other, and that the cause which affects the glandular structures of the large intestine may determine the mischief in the liver in certain climates and localities; such are obviously very different from those previously mentioned.

4. Lastly, I may just allude to the ordinary large and most frequently single tropical abscess, which is quite independent of dysentery, though, as just mentioned, it may coexist with or follow it. Each or all of these forms may be brought under our notice as the result of disease originally contracted in certain climates.—*The Lancet*, May 19, 1883.

Carcino-sarcoma of the Uterus in a Child.—Prof. Rosenstein has recorded an example of alleged mixed sarcoma and carcinoma of the uterus in a child two years old. The child was taken to the doctor chiefly because it had not passed water for three days. On clinical examination a tumor of the belly was detected, which was partly due to a distended bladder. After 700 cubic centimetres of urine had been drawn off by means of a catheter, a tumor was still to be felt, which reached about three fingers' breadth above the pubic symphysis. The child died after it had been under observation for fourteen days. At the post-mortem examination the uterus was found to be closely adherent to the bladder, an irregularly rounded tumor was seen projecting above the apex of the bladder, and apparently springing from the right lateral wall of the uterus, which was tilted towards the left; this nodule extended for about an inch beyond the limits of the fundus. Another nodule the size of a walnut was seen to project from the left of the fundus. The greatest length of the uterus was about two inches and a half, its thickness, from before back, about one inch and a half. Microscopical examination showed in some places, between the bundles of muscular tissue a very fine alveolar stroma, packed with epithelioid cells of various shapes and sizes, and which contained one or more nuclei. In other parts the structure resembled that of a spindle-celled sarcoma.—*The Lancet*, May 19, 1883.

Kairin.—Dr. Hallopeau gives an account of his investigations with regard to the antipyretic properties of hydrochlorate of kairin, introduced to notice by Prof. Filehne, of Erlangen. Its proper name is the methylhydrate of oxyquinoline ($C_{10}H_{13}NO$), being, like quinine, a derivative of quinoline. Prof. Filehne gives from five to eight grains (in a fever of medium intensity) every hour or hour and a half, the temperature becoming lower from a half to two degrees even after the first dose. After the third or fourth dose, it descends to the normal, or even lower, its fall being rapid in proportion to the dose, and accompanied by profuse sweating, which soon ceases if the temperature be maintained at the normal by new doses of the kairin. During the apyrexia, the patients experience a marked sense of comfort, the pulse recovering its normal frequency; but in order to maintain this state, the medicine has to be continued at the above-mentioned doses, or in grs. xv doses every two hours and a half, otherwise the fever returns as before. Dr. Hallopeau, from the few trials which he has made of this substance, quite confirms Prof. Filehne's statements, and comes to the conclusion that of all antipyretic agents, it is the one of which, at non-poisonous doses, the action is most certain, most powerful, and most rapid, and that it constitutes a precious resource in therapeutics, enabling us to counteract with certainty the dangers which hyperpyrexia in itself induces.—*Bull. de Thérap.*, March 30, 1883.

Sassafras Tea in Rhus Poisoning.—Dr. R. L. Hinton claims that sassafras tea is almost a specific for the rash of poison oak. The tea is an infusion of the bark (of the root) of the red sassafras. The affected parts are covered by compresses soaked in the cold infusion, while the warm tea is administered internally, sweetened or with milk.—*Medical Record*, April 14, 1883.

Treatment of Ozæna.—Prof. Massei says that if the mucous membrane is hypertrophied and the nasal cavity constricted, dilatation may be necessary. This is much better accomplished, as Massei recommends, by the douche of compressed air, simple or medicated, than by bougies. To cleanse the nasal cavities from the masses which encumber them, and to prepare the ground for other remedies, is the first indication. Weber's douche acts better than any other, and a simple alkaline or saline solution is better than astringents. Salt water or common salt dissolved in water (1 in 100) does very well. Afterward some antiseptic wash must be used. Massei prefers the following: salicylic acid grs. xvj, borax grs. xxxv, water Oj, with sufficient citrate of ammonia to dissolve the salicylic acid. He prefers the insufflation of powders or the application of ointments to pencilling with caustics. He finds calomel answer as well as any. If the exudation be thick and tenacious, and crusts form, ointments are preferable. He recommends inodorous iodoform, as in the following formula: iodoform, grs. xvj; balsam of Peru, grs. xxxv; vaseline, ʒv; the iodoform or balsam of Peru being mixed together before adding the vaseline—or borax and glycerine, 1 in 5. Inhalations of iodine may also be useful. The douche must be always used warm. Constitutional treatment must not be neglected. Iodide of iron and cod-liver oil should be given to scrofulous patients. Marine and sulphur baths are often of great service.—*London Med. Record*, May, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, JUNE 9, 1883.

THE AMERICAN MEDICAL ASSOCIATION.

CLEVELAND, June 7, 1883.—The Cleveland meeting of the American Medical Association has been large, interesting, and successful. In saying this, we do not refer so much to the Addresses and papers presented, which, however, were fully up to the usual standard both in quantity and quality, as we do to the general harmony of opinion which prevailed with regard to the important questions of medical politics which were impending, and the progress made in ascertaining and defining the views of the profession of the country upon these subjects.

As regards the questions which have been raised respecting the Code of Ethics, it was soon evident that the feeling in favor of retaining intact the time-honored laws of the Association was so universal that it was useless to discuss the subject, and the strength of this feeling was indicated by the dignified silence which was almost universally maintained with regard to it.

Every registered delegate and permanent member complied with the requirements of the constitution by signing a declaration of approval of the regulations of the Association, including its Code of Ethics, and although a few at first objected to do this on the ground that it was a new and unauthorized requirement, their scruples vanished when they learned that it was no new thing, but only a return to an old rule.

The report of the Committee on the Journal was approved without serious objection or criticism. The general sentiment being that while it is a somewhat doubtful experiment, it is one that is worth making, and that no great harm can come of a year's trial of the new plan.

The selection of Dr. Austin Flint, Sr., for President, for the coming year, gives general satisfaction, and is an indication of the prevailing current of feeling, which is deep and strong.

We congratulate the Association and the profession upon the stand it has taken and the work it has done, and offer our best wishes for the success of its new undertaking (the journal), the first number of which is to appear within a month.

In another column we have the pleasure of laying before our readers a full report of the proceedings of Tuesday, Wednesday, and Thursday, received by telegraph from our special reporters.

HYDROPHOBIA.

A RECENT discussion on hydrophobia, before the Philadelphia County Medical Society, has freshened this perennial, if somewhat hackneyed, subject. Also, the approach of the "dog-days," associated in the popular mind with this dread disease, requires us to say, at least, that it is a popular fallacy to connect this season with a special susceptibility of the canine race to the peculiar poison of hydrophobia. If the season be not specially timely for the disease, the important etiological and pathological questions raised in Dr. Dulles' paper are always awaiting an answer. Some of these are the specificity of the poison; the absence of definitely related anatomical changes, and the existence of a neurosis having the same objective symptoms, due not to a special poison, but to the effect of a disordered imagination.

The existence of a special virus of hydrophobia must yet be regarded as *sub judice*, notwithstanding the number of facts which seem to prove the affirmative. The question of spontaneous origin of the poison is, also, much disputed. These points are best considered together in the brief space at our disposal for this discussion. It is first to be observed that in certain noxious reptiles there is a special apparatus — salivary — for producing a venom. The saliva of some men has a toxic activity when administered subcutaneously to certain animals. The normal constituents which may exert such an action are the ferment, *ptyalin*, and sulphocyanogen; possibly also the potash salts. Saliva, both in the human subject and in some animals, seems to be modified in its properties by

profound emotional disturbance. There are apparently well-authenticated instances of hydrophobia caused by the bites of men inflicted in a state of intense and overpowering anger. That the saliva of healthy dogs may have a poison developed in it under circumstances of extreme anguish seems to be even less doubtful. Dogs confined, insufficiently supplied with food and water, and deprived of sexual gratification, have, there is reason to believe, become rabid. Again, a dog lost, pursued by evil-minded boys with shouts, and pelted with stones, without food or water, may, at length, as facts seem to indicate, grow distracted and vicious, and the saliva then acquire toxic properties. There are analogical changes in other secretions—the mother's milk, for example—which, under the influence of overmastering passion, may become actually poisonous. To the same category belong those poisons of an alkaloidal nature which are produced by the action of ferments in the course of infectious diseases. The most plausible theory is that which ascribes the toxic activity of the saliva to nervous (trophic) influence. Once acquired, it is probable that the poisonous principle becomes self-perpetuating, in accordance with the doctrine and laws of evolution.

It was held in the paper above referred to, and in the remarks of the principal speaker, who opened the discussion, that the morbid anatomy of hydrophobia is not sufficiently explicit to permit an accurate description. No reference, however, was made to the careful studies of Gowers, who goes so far as to affirm that "given the fact of an *acute* disease, a post-mortem diagnosis might, in the vast majority of cases, be made with certainty by the microscope." Benedikt, Coats, and others hold to the essential nature of the changes, also. The lesions which are regarded as characteristic are situated in the medulla (in the neighborhood of the respiratory centre) and in the salivary glands. These observations cannot, we think, be disposed of by mere negations. Not to find them, after a search guided by the requisite intelligence, is to place the case outside of the proper sphere of a malady produced by a specific poison. Under such circumstances, the malady becomes a mere neurosis.

Is there an affection presenting the objective signs and symptoms of hydrophobia produced merely by an all-absorbing mental and moral impression? We believe that the facts warrant the assumption that a neurosis, not distinguishable from the specific disorder in respect to its symptomatology, and frequently mistaken for it, really exists. The influence of the imagination in the production of morbid states is too well recognized to require statement here. A susceptible person receiving a bite or a scratch from a domestic animal, although free from disease, is ever after haunted with the fear of hydrophobia. Every detail connected with the disease is eagerly heard, treasured up in the memory, and gradually a complete picture of the malady is projected on the field of conscious impressions. Is it surprising, when some slight ailment disturbs the equanimity of the organic processes, that these realistic conceptions of hydrophobia should start up in vivid relief, and all the objective details of an attack, one by one, come to be realized in actual symptoms? That a fatal result should happen from a purely imaginary disease is by no means uncommon; but much depends on the locality of the seat of disturbance. A neurosis involving the functions of the medulla is vastly more important than one which is situated in the brachial plexus, for example. How can a mental impression, never so profound and all-pervading, stop the medulla oblongata functioning? Brown-Séquard would say "inhibition." When a powerful magnet is struck a tremendous blow, the magnetic property ceases on the instant. Similarly the spinal cord may cease to functionate. Still more pertinent is the ready physiological explanation. The paroxysms of hydrophobia require the evolution from the disordered centre of a large quantity of nervous force. No law is better established than that depression follows over-action, and that continued excitation must ultimately entirely exhaust the centre acted on. The more highly specialized the tissue in function, the more readily does it respond to irritation, and the more quickly are its powers exhausted. In these physiological facts do we have an adequate explanation of death due to a strictly functional neurosis.

In Dr. Dulles' paper and in the discussion which followed it, there was no suggestion of a remedy. Silence on this topic indicates the discouraging nature of the subject. The great clinical point—the separation of the specific infective prototype from the mimic disease—is the most fruitful field awaiting appropriate cultivation. We postpone to some more convenient season the consideration of the therapeutical questions connected with the management of this disease.

CHLOROFORMIZATION.

M. PAUL BERT has been engaged for several years in the study of the action of anæsthetic agents. The problem to which he has lately applied himself is to determine the physiological modifications due to the minimum and to the maximum quantity of vapor. By means of a suitable apparatus, the animal experimented on inhales the vapor during a period of ten hours. The quantity of vapor given may be less, or greater, than that necessary to induce an

anæsthetic condition which is within the limits of safety. His results demonstrate the superiority of the method employed by some administrators—the method by which the anæsthetic state is promptly induced by a full supply of vapor, after which a minimum supply is furnished, but sufficient to maintain insensibility. A quantity which is quite insufficient to bring on the condition of anæsthesia will maintain it when once induced by larger doses.

We know of a uniformly successful chloroform administrator, whose use of the anæsthetic, at the beginning of the inhalation, seemed to be almost reckless. Dashing on to the towel-cone an ounce or more of chloroform, he brought the patient very promptly under its influence. In this practice the source of safety lies in the immediate suspension of the reflexes. As Bert's experiments show, the fall of temperature caused by anæsthetics is in a direct ratio to the duration of the inhalation, and the danger corresponds. The loss of body-heat is much greater with a small quantity of the anæsthetic slowly administered than with twice the quantity given rapidly.

The superiority of the rapid inhalation method then appears to consist in two safety-factors: in the prompt abolition of the reflexes; in the less quantity of heat lost. Experiment and experience here coincide. In such observations the presumption is that the heart is sound. Pathological states, especially a fatty condition of the heart muscle, and degenerative changes in the motor ganglia may confound the best considered rules based on observation and experiment merely.

SALICYLIC ACID IN SKIN DISEASES.

DR. RABITSCH has used with success, in some affections of the skin, an alcoholic solution of salicylic acid, having the strength of ten per cent. (10 parts of salicylic acid, 90 parts of alcohol). Sometimes the affected parts are merely sponged with this solution; in other instances, bandages, moistened with the solution, are applied. The cases thus treated consisted of herpes tonsurans, involving most of the scalp, the ears, and the neck, and large patches had formed on the thighs and limbs; of two of pityriasis versicolor, of two of eczema marginatum. Most of these cases appeared to be of long standing, and yet they yielded completely and, comparatively speaking, very rapidly to applications of the salicylic acid solution. Dr. Rabitsch prepares the parts for the treatment by the preliminary application of glycerine, followed by soap and water, to secure the detachment of crusts, and then the solution is freely used in the modes above described. How much of the result may be due to the alcohol, and how much to the salicylic acid, does not appear.

TREATMENT OF CORYZA BY THE SULPHATE OF ATROPINE.

A PHYSICIAN of Rheims, M. GENTILHOMME, has recently proposed the use of atropine as a remedy for *acute coryza*. He conceived this notion when reflecting on the power of this agent to arrest the secretions of the nasal mucous membrane. He appears to be unaware that this fact has long been known and frequently utilized in the treatment of affections of the broncho-pulmonary mucous membrane characterized by excessive secretion. Atropine frequently acts most efficiently in summer catarrh, in hay asthma, and in ordinary asthma accompanied by bronchorrhœa. Dr. Gentilhomme, only reiterates a fact, therefore, and has made no discovery. He has, however, rendered a service by freshening the professional recollection of a useful practice. The preparation employed may be a solution or a granule. The former is preferable since changes in the dose given is often necessary. If one grain of sulphate of atropine be dissolved in four drachms of water, two minims will contain $\frac{1}{120}$ grain, usually a sufficient dose to begin with.

THE ANATOMY BILL.

WE are very glad to learn that the Legislature of Pennsylvania has passed the new Anatomy Act substantially as drafted by the anatomists. The Governor has signed the bill, and it has now become a law.

As soon as we obtain a certified copy, we shall publish it in full for the information of our readers. It is, we believe, the most liberal and practical Act in this country, providing not only for obtaining and using material all over the State, but also an excellent plan for its equitable distribution. We hope other States will soon follow suit.

DR. RAUCH, the Secretary of the Illinois State Board of Health, has favored us with a copy of a letter addressed to him by one L. C. Washburn, President of the St. Louis Eclectic Medical College, in which the latter functionary characterizes the Board which Dr. Rauch represents as "dastard bigots and villains," of which Dr. Rauch is the "chief," because it refused to issue to those holding diplomas from said school, certificates permitting them to practice in Illinois. The letter is another one of those masterpieces of bad spelling and general illiteracy which are the expression of outbursts of rage on the part of those who seek to make a traffic of the issue of diplomas, when they are foiled in any of their efforts. The field of Illinois is cut away from them, and this angry wail goes forth malignant but harmless, as the expiring cry of a beast of prey. Would that every State would adopt a policy like that of Illinois.

SOCIETY PROCEEDINGS.

THE AMERICAN MEDICAL ASSOCIATION.

Thirty-fourth Annual Meeting, held at Cleveland, Ohio, June 5, 6, 7, and 8, 1883.

(*By Telegraph.*)

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, JUNE 5TH.—FIRST DAY.

GENERAL SESSION.

THE Association met in Case Hall, Cleveland, and was called to order at 10.30 A.M., by X. C. SCOTT, M.D., Chairman of the Committee of Arrangements.

The session was opened with prayer by the Right Reverend Richard Gilmour, Bishop of Cleveland.

The PRESIDENT, JOHN L. ATLEE, M.D., of Lancaster, Pa., was then introduced, and took the chair.

GENERAL EDWARD S. MEYER delivered an address of welcome.

The ex-presidents and vice-presidents of the Association were then invited to take seats on the platform. The appearance of Prof. S. D. Gross upon the stage, was hailed with prolonged applause.

The programme of the meeting was then announced.

THE REGISTRATION OF MEMBERS.

DR. X. C. SCOTT, *Chairman of the Committee of Arrangements* announced the reception of protests against the registration of members who had not signed the Code of Ethics, which with other protests were referred to the Judicial Council. The Chairman also announced that all delegates in registering, had been, or would be, required to sign a blank to the effect that "in acknowledgment of having adopted the Constitution and By-Laws and Code of Ethics of this body, and of my willingness to abide by them, and of my endeavors to carry into effect the objects of this Association, I hereunto affix my name."

Several delegates refused to sign this form, and were therefore not registered.

The SECRETARY then announced the reception of letters from a number of delegates, who for various reasons were prevented from being present.

The PRESIDENT, DR. JOHN L. ATLEE then delivered

THE ANNUAL ADDRESS

(see page 639), which was received with considerable applause, and the Association passed a vote of thanks for it.

THE OHIO STATE MEDICAL SOCIETY

in session in Cleveland, were, on motion, invited to become members of the Association by invitation.

DR. J. S. BILLINGS, U. S. A., presented a communication from the President of the British Medical Association and Dr. Mahomed, inviting coöperation with the committee of the Association on the

COLLECTIVE INVESTIGATION OF DISEASE.

Referred to the standing Committee on Atmospheric Conditions and their relations to the Prevalence of Disease.

DR. H. D. DIDAMA, of New York, presented a communication from Dr. Tyndale, of New York, containing a petition to Congress, the Secretary of War, and the Signal Service Department, requesting that a committee of five professional gentlemen be appointed to establish

CLIMATIC OBSERVATIONS

at the general health resorts and watering places, and to collect data in regard to the sanitary value of the localities in regard to pulmonary diseases.

THE LIST OF DELEGATES

registered was then read, and on motion, those names against which no protest had been received were confirmed.

The Association then adjourned.

In the evening the Association was entertained by the citizens and medical profession of Cleveland at a brilliant reception and banquet at the Euclid Avenue Opera House.

SECTION MEETINGS.

SECTION ON PRACTICAL MEDICINE, MATERIA MEDICA, AND PHYSIOLOGY.

The Section met at the Opera House, at 2.30 P.M., DR. J. H. HOLLISTER, of Illinois, *Chairman*, presiding.

DR. ROBERT D. MURRAY, of U. S. Marine-Hospital Service, read a paper on

YELLOW FEVER,

in which, from his experience gained in the treatment of cases during the epidemics of 1873, '75, '76, '78, and 1882, he protested against theoretical therapeusis. After the patient is once attacked, all attempts to arrest the fever will only be time lost. Free catharsis should be produced; mustard pediluvia used, free diaphoresis promoted by drinking lemonade, and nausea allayed by iced-porter. During convalescence, water or Catawba wine should be given. Whiskey he did not consider so good. He urged the importance of the recumbent position, and the avoidance of all muscular exertion.

DR. HENRY F. CAMPBELL, of Georgia, regarded yellow fever as an asthenic fever, and compared it to the type of our own malarial fevers, though he would by no means identify it with malarial fever, which comes from the malaria of our swamps, since yellow fever he believed to be caused by blood-poisoning. Bleeding he believed to be, in some cases, beneficial; but he thought it was often used injudiciously. He considered it important that the colon and stomach of the patient should be invariably emptied. For the constipation, he recommended the administration of oil. As yellow fever is a congestive disease, and as quinine lessens the tendency to congestion, he was in the habit of administering grs. xv–xx quinine by enema, with starch, but he did not recommend the large doses advised by some German authorities. Champagne, soda water, and Apollinaris proved acceptable. His results by this method of treatment were fairly good, but he had lost about half his patients.

DR. WM. MORROW BEACH, of Ohio, then read a paper on

MILK SICKNESS,

which he believed to be a disease *sui generis*. In his own county one-fourth of the pioneers died of it. The disease is limited to certain localities, as for instance, Ohio, Indiana, Illinois, and Michigan, and has probably never been seen in New England, and its existence as a specific disease has generally been disregarded. In the lower animals it is called the "trembles;" it attacks alike wild and domesticated animals. Drinking milk, or eating the products of milk from infected animals often gives the disease. The "trembles" is seldom met with in wet seasons. In prairies it is never seen. Animals may safely roam through infected districts, if they are corraled until the morning dew is dispelled. He accepted the theory that the disease is due to a microscopic fungus.

DR. ALONZO PALMER, of Michigan, considered the paper just read to be the best that had yet appeared on the subject, and suggested the desirability of the appointment of a committee for the minute investigation of the disease.

SECTION OF OBSTETRICS AND DISEASES OF WOMEN

met at Frohsinn Hall, at 2.30 P.M., J. K. BARTLETT, M.D., of Wisconsin, *Chairman*, presiding.

On motion, J. A. JELKS, M.D., of Hot Springs, Arkansas, was chosen Secretary, in place of Dr. G. A. Moses, of Missouri, not present.

In the absence of DR. W. H. BYFORD, of Illinois, who was detained at home by professional duties, the Secretary read for him his paper entitled

CHRONIC INTRA-PELVIC INFLAMMATION.

The terms parametritis and perimetritis are erroneously supposed by many to include the whole subject of intra-pelvic inflammation. These terms are misleading, because, as now often used, they present to the mind the idea that all cases of inflammation not confined to the uterus must belong to one or another of them. Actual observation teaches the important fact that peri- and parametritis usually exist together, and are usually complicated with inflammation of the uterus, and not infrequently the ovaries and Fallopian tubes are involved. The obvious conditions of chronic parametritis are: 1. Suppuration and chronic pelvic abscess, located more frequently, but not always, in the broad ligament, and the consequence of cellulitis. The chronic pelvic abscess is generally the sequel of acute inflammation, and attains chronicity from imperfect evacuation of pus after acute inflammation has terminated in suppuration. The remedy in such cases is found in surgery, and consists in making a more direct outlet through the vagina, large enough to at once completely evacuate the pus, and enable the surgeon to cleanse and disinfect the cavity. He cited several cases in illustration of his remarks, and in closing he said that the main object that he had in writing this paper was to caution his associates against the danger of converting a chronic pelvic inflammation into a disastrous acute form. He gave the following summary of suggestions and inferences deducible from them.

1. The sometimes terrible effects of examinations or operations in the pelvis, do not often, if ever, take place when there is not a perceptible predisposing inflammation. 2. The inflammation may be so slight as to be easily overlooked. 3. It may be an original condition, the sequence of an acute attack long gone by, or it may be the product of some immediately previous examination or operation, the effects of which have not subsided. 4. To avoid the dangers of acute inflammation, we should, in making a first examination for pelvic disease, conduct it in such a way as not to give the patient much pain; and when she complains of much suffering, we should at once desist, even at the sacrifice of completeness of diagnosis. 5. Complaints of much tenderness to the touch, or from the use of instruments, is sufficiently diagnostic of inflammation upon which to base treatment for that condition. 6. If, with such tenderness, a thorough examination or an operation is imperative, it should be done under profound anæsthesia. There is no question in the author's mind that much less danger of ill-effects is incurred in making examinations or performing operations on susceptible subjects under the free use of anæsthetics. 7. Examinations or operations should not be repeated until the effects of the first have entirely subsided. 8. As chronic parametritis is a frequent complication of most of the morbid conditions of the uterus, it should be always suspected, and its diagnosis be carefully considered in all cases of metritis. 9. When chronic parametritis is present, it should be the chief, if not the exclusive object of treatment until removed. 10. It is not safe to use the sound, sponge-tent, or intra-uterine stem when there is perimetric inflammations. 11. It is especially dangerous to replace a displaced uterus when it is bound down by inflammatory adhesions, by any means which will overcome its fixedness by force. 12. The use of pessaries or supports of any kind which find their lodgement in the pelvis, is generally followed by disastrous consequences where there is even slight perimetric inflammation. 13. All local treatment of the uterus must be conducted with the greatest care where this complication is present.

DR. HENRY G. LANDIS, of Columbus, Ohio, read a paper on

POST-PARTUM POLYPOID TUMORS.

He said the physician is sometimes blamed for not completely delivering the placenta, when the real condition is due to other substances than placental tissue.

1. Blood polyps may form after delivery, consisting only of coagulated blood.

2. Blood polyps *may* be associated with retained fragments of placenta or membrane.

3. The same condition may occur with strips of decidua, prematurely detached.

4. The decidual membrane may undergo hypertrophy in places, giving rise to a sessile tumor of some magnitude and causing secondary hemorrhage, septicæmia, etc.

To the few cases on record the writer added the details of two cases observed by himself.

DR. JOHN MORRIS, of Maryland; Dr. Watkins, of Kentucky; and Dr. H. O. Marcy, of Massachusetts, cited similar cases.

DR. H. O. MARCY, of Mass., then read a paper on

THE RESTORATION OF THE PERINÆUM BY A NEW METHOD,

in which he claimed that the perineal body was an anatomical entity, and was the keystone in the arch of perineal support. Its physiological importance in parturition had been recently well demonstrated by Dr. Hart, of Edinburgh, and a thorough understanding of this would do much to lessen the frequent occurrence of perineal laceration. He presented a new method for repairing the perineum by the use of lateral support. This is accomplished by the use of wire of German silver, which possesses elasticity sufficient to make lateral tension, and the ends are so bent as to each form with the other, support; thus a kind of "safety-pin" holds the refreshened parts in position.

DR. R. S. SUTTON, of Pa., then read a paper entitled

ENTEROTOMY AS A COMPLICATION IN OVARIOTOMY OR OÖPHORECTOMY.

He cited two cases of removal of several inches of the small intestine, one by Prof. Billroth, and one by himself, both of which recovered. In his own case he successfully removed four inches of the small intestine a few months ago. This was stated to be the first successful operation of this kind ever performed in this country.

THE SECTION ON SURGERY AND ANATOMY

convened at Case Hall, at 2.30 P. M., the CHAIRMAN, W. F. PECK, M.D., of Iowa, presiding.

DR. REUBEN A. VANCE, of Ohio, read a paper on

THE RADICAL CURE OF HERNIA BY A NEW METHOD.

He said that the study of nature's method of curing an oblique inguinal hernia shows that there are two important processes at work. One a band of adventitious tissue about the neck of the sac, constantly tending to contract and close the abdominal opening at the inner ring; the other, the return to place of the two layers of the transversalis fascia, the separation of which originally permitted the viscera to protrude, and reunion of which forms a valve strong enough to prevent the recurrence of the hernial protrusion. Trusses favor a

cure of the lesion. He then considered briefly the anatomy of oblique inguinal hernia, and the pathological processes in operation in such cases. He then described at length the method which he said had been very successful in his hands. He had operated on thirty-two cases by Dowell's method, and in nineteen cases the result, as far as the patient was concerned, was all that could be desired.

DR. FITCH, of Maine, asked the proportion of recoveries in his cases.

DR. VANCE replied that he could not tell how soon, if at all, the hernia might return in the nineteen cases, but he hoped to publish the details of all his cases at some future time.

DR. DUDLEY P. ALLEN, of Ohio, read a paper entitled

A COMPARISON OF ANTISEPTIC AND NON-ANTISEPTIC METHODS OF TREATMENT.

He said that it was beyond doubt, that in this country antiseptic methods are in less favor than a few years ago. This change seemed to depend to a certain extent upon favorable statistics produced by Mr. Keith and Mr. Tait in ovariotomy since they have given up the use of antiseptics. Mr. Keith, however, believes in the principles of antiseptics, but does not use the spray in operating upon the abdomen, because he fears poisoning. Everything coming in contact with wounds is cleansed thoroughly. The inference from Mr. Keith's practice would seem to be that in abdominal operations he considers the danger of infection from the atmosphere less than the danger of poisoning by carbolic spray. Dr. Allen described Mr. Lister's careful use of antiseptics; and the methods of Prof. Volkmann, of Halle, Saxony, and of Prof. Billroth. The antiseptic method may be grouped under one of three heads: 1st. The methods that prevent the entrance of germs to wounds as represented by Mr. Lister; 2d. The method of Volkmann, which washes them from a wound while it is exposed, and then so protects the wound by dressing as to prevent germs reaching it; 3d. The method of Billroth, which disregards the entrance of germs into wounds during the operation, and through the discharge during the process of healing, but destroys these evil influences by the presence of a powder that renders the wound continuously antiseptic.

In conclusion it would seem: 1. That the fact that operations on the abdominal cavity succeed without the spray does not influence the employment of antiseptics with regard to other operations where there is a continued opportunity for infection. 2. It would appear that the spray is the least important of all the details in antiseptic surgery, and that if the other details are attended to the proper dressing of wounds, pressure, and drainage, may, by securing absolute quiet for a wound, turn dangers into benefits. 3. That different methods are of different applicability, and that whereas the spray might be most desirable in opening joints, and in the atmosphere of hospitals, with bad hygienic surroundings, flooding might be equally efficient in certain other wounds, and that some prominent antiseptic, as iodoform, would be most serviceable when other antiseptics are inapplicable, as in the removal of the tongue. 4. That although there are certain dangers in the use of antiseptics, these are more than equalled by the dangers attendant upon their omission, especially in large hospitals, and that dangers of poisoning are certainly decreasing as the application of antiseptics is becoming better understood; and, further, that investigation may develop a method of securing antiseptic results less onerous and devoid of the disadvantages that now surround them. He summed up his paper by expressing the belief that the various antiseptic methods secured far better results than any other method.

DR. HENRY A. MARTIN, of Massachusetts, spoke strongly in opposition to antiseptic surgery in general, and Listerism in particular. He said Listerism was not cleanliness as has been claimed, but the killing of certain supposed germs. He had opened the knee-joint by aspiration in a large number of cases of synovial effusion of the knee without the use of the antiseptic method, and in no instance had there been the first indication of an approach of trouble.

DR. NANCREDE, of Philadelphia, spoke as strongly on the other side and predicted that the future surgery will be some modification, not of Listerian dressings, perhaps, but of the principles of Listerism, which we all use and say we do not. (Applause.)

DR. QUIMBY, of New Jersey, asserted most positively that the use of antiseptics strong enough to destroy germs in the atmosphere is likely to produce poisoning of the patient.

DR. MCCLURG, of Pennsylvania, said he was not particular to cleanse thoroughly his sutures, sponges, and instruments, and had never found any trouble from their use.

DR. GARCELON, of Maine, spoke against Listerism, and testified to a successful country practice without the use of antiseptics.

DR. MURDOCK, of Pennsylvania, favored antiseptic treatment, believing it to be the only proper treatment of wounds in general hospitals.

DR. WATSON, of New Jersey, earnestly advocated the principles and practice of Listerism. In cases of failure, the failure had not been the fault of the system or dressing, but had occurred through inattention to some of the details.

The next paper was by PROF. S. D. GROSS, of Philadelphia. The Chairman in introducing Dr. Gross said his paper had been written for the American Surgical Association and was to be its property, and it was only with this understanding that Prof. Gross had consented to read it here. Some of the delegates manifested a desire to discuss the paper, but the paper not being the property of the Association, debate was held not in order.

DR. HENRY A. MARTIN, of Massachusetts, next presented a paper of great length on the subject of

THE TREATMENT OF SYNOVIAL DISEASES BY A NEW METHOD,

illustrating the use of Martin's rubber bandage, and reciting many cases of its successful application in cases of synovial disease.

DR. GARCELON, of Maine, inquired if Dr. Martin recommended immobility of the joint or limb in the use of his bandage.

DR. MARTIN replied, "Oh no, sir, never; I invariably instruct the patient to use the limb, and demand that he shall walk a mile a day, and as much more as he pleases."

DR. E. M. MOORE, of New York, endorsed all that Dr. Martin had said in favor of the bandage, but said he had not found it successful in cases attended by pulpy degeneration of joints, these cases all occurring in childhood or early life.

DR. MARTIN said that in cases of periosteal disease the bandage was harmful.

The Section then adjourned.

SECTION ON OPHTHALMOLOGY, OTOLOGY, AND LARYNGOLOGY

met at the Board of Education rooms, at 2.30 P. M. On account of the absence, from sickness, of the Chairman, A. W. CALHOUN, M.D., of Ga., J. J. CHISOLM, M.D., of Maryland, was appointed Chairman.

DR. LAWRENCE TURNBULL, of Pa., read a paper on *Paralysis of the Facial Nerve in Connection with Diseases of the Ear.*

DR. W. C. JARVIS, of New York, followed with a paper on *Tonsillotomy by Ecrasement*, and DR. CARL SEILER, of Pa., with one on the *Action of Nitrate of Silver on the Mucous Membrane of the Throat*, and DR. C. WILLIAMS, of St. Paul, with one on *Myringitis*, which was read by title on account of the absence of the author, and referred to the Committee of Publication.

SECTION ON DISEASES OF CHILDREN

met in Council Chamber, City Hall. In the absence of the CHAIRMAN, DR. R. F. BLOUNT, of Indiana, DR. C. W. EARLE, of Chicago, was called to the chair.

DR. C. W. EARLE read a paper on

CEPHALHÆMATOMA IN NEWBORN.

This he defined as a soft, elastic, fluctuating tumor, generally painless, and situated upon one of the cranial bones. He stated that it occurred with greater frequency than the literature of the subject would lead one to suppose. He had seen four cases in twelve years' practice, and contrary to the experience of other observers, all four were situated on the left parietal bone, whereas it is stated by some writers that in the majority of cases the tumors are on the right parietal bone, inasmuch as this bone is exposed to pressure by the rigid os uteri in the greatest number of deliveries. In the cases in the writer's practice, the tumor has not made its appearance immediately after birth, some three or four days usually elapsing before the writer's attention had been called to the difficulty. It has in a few cases been noticed upon both parietal bones, but not in the writer's practice. Prof. Byford, of Chicago, has observed at least one such case, and Jacobi and others mention cases of double cephalhæmatoma. When the tumor is first noticed it is a soft and painless enlargement. In the course of a few days a firm bony ridge is usually noticed surrounding the base of the tumor. The seat of effusion is between the bone and the periosteum, and the enlargement is caused by rupture of a bloodvessel; the bony ring is simply material thrown out from the periosteum to repair the injury. The author had noticed a little hard projection springing forward from the ridge, showing that the deposit of osseous material does not take place evenly in all directions; as the process of repair goes on the tumor loses its soft fluctuating feel, and in the course of a few weeks nothing can be detected except a slight want of symmetry in the two parietal bones. The most important question connected with the subject, the speaker said, was its diagnosis, and it appeared to him that there were four diseases with which it was likely to be confounded, namely: caput succedaneum, congenital encephalocele or hernia cerebri, erectile tumors, and cranial tabes. To show the distinction between these four diseases and the one under discussion the speaker said, the caput succedaneum is an œdematous condition, and it does not fluctuate, being only a disease of the scalp, cellular tissues, and bloodvessels; congenital encephalocele never occurs, with a possible exception, on the cranial bones; a vascular tumor has sometimes the same boggy feeling noticed in caput succedaneum, but it has no bony ridge; cranial tabes is the soft places found upon the cranial bones in rickety children. After fully considering the etiology, the author next considered the treatment, which in these cases really amounts to judicious letting alone, nature in the great majority of cases, cures the difficulty without aid from our art. A desire on the part of parents, however, exists to interfere, and the physician will be importuned to poultice, blister, open, and otherwise interfere with the processes nature is following to perfect a cure; some mild anodyne may be added. When tension is very great, or the tumor larger than usual, or when the child experiences considerable pain, it is better probably to open the tumor, cleanse out the cavity, dress it, so as nearly as possible to preclude suppuration.

DR. WILLIAM LEE, of Baltimore, did not see how cranial tabes could be confounded with cephalhæmatoma, as the former was scarcely ever seen in children. Although little or no interference might be necessary in most cases, still surgical interference becomes necessary in some.

DR. REID, of Cincinnati, had seen several such growths, and preferred leaving them alone.

DR. L. BOOTHBY in a practice of nine years, had seen several cases, and had insisted on leaving the growths alone.

Adjourned.

WEDNESDAY, JUNE 1ST.—SECOND DAY.

GENERAL SESSION.

THE PRESIDENT called the Association to order at 9.30 A. M., and prayer was offered by Rev. Charles S. Pomeroy, D.D.

DR. FOSTER PRATT, of Michigan, called up the

AMENDMENT TO THE CONSTITUTION,

offered by him two years ago, to the effect

"That the law requiring the nominations for officers to be made *from those members present at the annual meeting* shall apply only to the President, the Vice-presidents, Chairmen and Secretaries of Sections, the Assistant Secretary, the Chairman of the Committee of Arrangements, and the Judicial Council."

PROF. S. D. GROSS, of Pennsylvania, read a communication signed by himself, Dr. Austin Flint, Jr., and Dr. Oliver Wendell Holmes, urging upon the Association the importance of petitioning Congress to provide a suitable

FIRE-PROOF BUILDING FOR THE ARMY MEDICAL MUSEUM AND LIBRARY.

DR. H. A. JOHNSON, of Chicago, then presented a series of resolutions petitioning Congress to make an appropriation for such a building and for the completion of the Index Catalogue of the Library, and also for an annual appropriation of $10,000 to enable the librarian to purchase for the library, as they are published, all medical books of this country and the more important of Europe.

THE NOMINATING COMMITTEE

was announced as follows:

Alabama, W. O. Baldwin; *Arkansas*, D. A. Linthicum; *California*, C. H. Steele; *Connecticut*, T. Morton Hills; *Dakota*, J. S. Van Velson; *Delaware*, W. M. Marshall; *District of Columbia*, D. C. Patterson; *Georgia*, Eugene Foster; *Illinois*, C. T. Parks; *Indiana*, H. D. Wood; *Iowa*, W. S. Robertson; *Kentucky*, L. S. McMurtry; *Kansas*, W. L. Schenck; *Louisiana*, J. W. Dupree; *Maine*, A. J. Fuller; *Maryland*, J. J. Chisolm; *Massachusetts*, C. A. Savory; *Michigan*, F. K. Owen; *Missouri*, D. H. Gregory; *Nebraska*, V. H. Coffmann; *New Mexico*, W. R. Tipton; *North Carolina*, E. Grissom; *New Jersey*, B. A. Watson; *New York*, H. D. Didama; *Ohio*, Wm. M. Beach; *Pennsylvania*, S. D. Gross; *Rhode Island*, A. Ballou; *South Carolina*, R. A. Kinloch; *Tennessee*, D. J. Roberts; *Texas*, H. C. Ghent; *Virginia*, Alexander Harris; *W. Virginia*, J. M. Lazzell; *Wisconsin*, S. C. Johnson; *U. S. Army*, J. R. Smith; *U. S. Marine-Hospital Service*, T. W. Miller.

DR. N. S. DAVIS, of Illinois, Chairman of the Board of Trustees of

THE ASSOCIATION JOURNAL,

presented the annual report.

After reading the resolutions adopted last year, instructing the Board of Trustees as to their duties, all of which were published in THE MEDICAL NEWS at the time, Dr. Davis read the conclusions at which the Board have arrived, after holding several meetings.

The Board consisted of Drs. N. S. Davis, of Chicago; E. M. Moore, of New York; J. M. Toner, of Washington; H. F. Campbell, of Georgia; J. H. Packard, of Philadelphia; L. Connor, of Michigan; P. O. Hooper, of Arkansas; A. Garcelon, of Maine; and L. S. McMurtry, of Kentucky.

A sufficient number of reports of the special committee of the Board, was prepared as soon as possible and sent to each member of the Board. A programme for a weekly medical journal containing an average of thirty-two double-column pages of reading matter, was agreed upon. Each number was to contain a department for original articles, embracing all such papers, addresses, reports, etc., as should be referred for publication by the Association, and such other original matter of value as might be contributed for that purpose. A department containing a summary of the progress in the various departments of medical science; an editorial department proper, especially devoted to the discussion of such topics as would be likely to aid in promoting the interests and efficiency of medical organizations, both National and State; a department of correspondence from the more important medical centres, domestic and foreign; and a department of miscellaneous items of intelligence, especially in relation to the doings of all medical and scientific societies in this country, and of such notices of the duties of committees, the presentation of papers, the practical working of associations, the time and place of meetings, as will greatly aid in rendering all the work of these bodies more systematic.

This done, the Board published forty thousand circulars containing the principal features of the plan of the object to be accomplished, together with forty thousand blank pledges of support of such journal if published, and mailed them to members of the profession in all the States and Territories. It required three-fourths of these to supply fourteen States, leaving only the remaining fourth for twenty-seven States. The comparison of returns from States well supplied and those not so well supplied indicates that an increase of twenty-five per cent. would have been realized if all the States had been supplied. As it is, two thousand one hundred and fifty answers have been received; twelve were direct expressions of opposition to the proposed change, thirty-eight were equivocal, while twenty-one hundred were unqualified pledges of support, either by prompt payment of the annual dues or by subscription.

By reference to the list of members, it was shown that 500 members had not answered, while nearly the same number not members have pledged their support. This makes the aggregate number of subscribers 2,500, as actual basis of income; supposing that these members who failed to reply will still continue their membership. This would indicate a revenue of $12,500.

It is deemed best to issue 3,500 copies weekly, in order to have a sufficient number of extra copies for all purposes, including sample copies. This number, on good paper, can be issued for $8,000 a year, leaving $4,500 for editorial work and current expenses of the Association. Advertisements in a journal reaching all parts of the country, as this one would, will probably bring $5,000 more, leaving a balance after paying $6,000 for editorial work. Bids have been received from two reliable printing establishments in Washington, three in Philadelphia, two in New York, and two in Chicago.

At a meeting, held at the Grand Pacific Hotel, Chicago, January 17, 1883, at which Drs. Toner, Packard, McMurtry, Davis, and Connor were present, it was unanimously decided to publish the journal.

The following resolutions were then adopted:

1. The editor is to take direct supervision of the work, and for business purposes should employ a clerk competent to assist in all business matters.

2. For assistance in editorial work he should select an assistant competent to collect and write up the progress being made in all departments of medical science, and should engage reliable correspondents.

3. He should establish correspondence with Secretaries or proper officers of all State medical societies, with view to procuring official and private contributions to its pages.

4. Through his clerks, he should solicit advertisements from all medical educational institutions and hospitals open for clinical instruction, book publishers, pharmaceutists, instrument-makers, and all other legitimate business interests; but all advertisements of proprietary, trade-mark, copyright, or patented medicines should be excluded (this announcement was received with loud applause). Neither should any advertisement be admitted with one or more names of members of the profession as endorsers, having their official titles or positions attached (renewed applause).

The publication was awarded to the firm of A. D. Newell & Co., of Chicago, and Chicago was chosen as the place of publication.

It is thus seen that the Board have complied with all the instructions given them.

At the conclusion of Dr. Davis' explanation of the work of the Trustees, the Association enthusiastically adopted the report, notwithstanding an attempt by Dr. Wyle, of Connecticut, to have the lengthy statement (which occupied nearly half an hour in delivery) printed during the night, distributed to the Association, and the whole matter brought up as the special order for Thursday, at ten o'clock.

DR. L. S. MCMURTRY, the Secretary of the Board of Trustees of the Association Journal, formally announced that the Board had unanimously elected Dr. N. S. Davis, of Chicago, as

THE EDITOR OF THE ASSOCIATION JOURNAL.

DR. DAVIS, in reply to this announcement, said: The announcement of my name to this position brings a duty upon me that has caused me more hesitation and has required of me a longer period of consideration to bring myself to the point of accepting the duties, than any other question of my life. When the question of journalizing the proceedings was first proposed, several years ago, by that Nestor of our profession, Prof. Samuel D. Gross, it struck me as an unsafe proceeding. When the question was again broached, a year or two later, still the bare mention of it, and the thought of the immense duties that such a position would enjoin upon whoever the Association should appoint to the great work, overcame me with the belief that such a project was impracticable. But the almost unanimous response that the project has received has made it seem to me, however, that, in the progress of time and the widening circle of events, the time has come when it is not only possible, but, considering the forces and influences involved in the present status of the profession, it is demanded that somebody shall assume the duty. For the Association must have a voice, through which it may reach, not only its own constituents, but a voice that may be an honor to our profession (applause), and extend from every ramification of our Society to countries on the other side of the ocean; and unless we do thus introduce some means, some journal of the Society, we must find the motions and resolutions which we make

here from time to time laid away, eight months hence, somewhere on the shelves of libraries, with nothing left to indicate that they still have as strong an existence as when they were passed. With the full impression of the importance of the work, then, and keeping in view my life motto, that has been my guide for forty or fifty years of activity: "Whatsoever thy hand findeth to do, do it with all thy might, trusting to a Higher One for the result."

I have consented to assume the charge, but fair, fair as it looks and encouraging as have been the responses to these circulars from all quarters of the country, showing the project great favor, I must ask you, Gentlemen, not to expect to see at the end of thirty days or thirty months a complete journal free from faults. *The British Medical Journal* has been referred to as our model, but I beg you to remember that this journal required years of growth before it attained its present standing, and you must not expect too much of us in the first issues. Our arrangements are such now that we suppose the first number of the journal will reach you on or soon after July first, and if there should be any delay in its appearing, I beg you to remember that no man can prevent certain little occurrences which may cause a delay of a day or two, and I assure you that all I have to do will be done as honestly and as thoroughly as I am able, for if I have a few years longer to work for the profession and humanity, it is for these that I work. If I can see from this project an addition to the development of our National organization, or of its constituences in the State and local societies, and that they have a journal that is in some measure a fitting voice through which they may express their thoughts and record their proceedings, I shall complete my course of life fully satisfied that I have not lived in vain. I hope the Association in any action it may take during the remainder of this session may be cautious about doing many things, especially any thing that shall involve unnecessary expenses until we see how the balance sheets shall turn out at the end of another year.

I would now, in view of the position and duties assigned me by the Board of Trustees, respectfully resign my position on that Board, and I would announce that I have already obtained the conditional assent of Dr. Wm. Lee, of Washington City, to take charge of writing that most important branch, the progress of medical science throughout the world, well knowing that his opportunities in commanding an extensive range of medical literature admirably fit him for the position.

DR. SOLIS COHEN moved that the Board of Trustees be instructed to print in a thin octavo volume,

THE MINUTES

of the American Medical Association, as held. This form would be more acceptable to the profession, and would free the Journal of a great deal of uninteresting matter.

DR. HIBBERT, of Indiana, said it seemed to him unwise to encumber the Board with any more duties.

DR. QUIMBY, of New Jersey, said: I think the motion of Dr. Cohen a good and sensible suggestion, because it will not cost much to print the bulletin he proposes, and it will leave the Journal unemcumbered with a great amount of mere reports of little interest.

It was moved to refer this question to the Board of Trustees.

DR. QUIMBY said the Board of Trustees have nothing to do with the matter, and it is the duty of the Association to decide it.

He was ruled out of order, and the original motion was passed.

DR. BUSH, of Delaware, moved a

VOTE OF THANKS TO DR. DAVIS,

for his kindness and self-denial in accepting the duties imposed upon him.

THE EFFECT OF SIGNING THE CONSTITUTION.

DR. A. PALMER inquired whether those who signed the Constitution and Code of Ethics bound themselves to it by everything in the Constitution, or that may hereafter be placed in it.

THE SECRETARY replied that he was bound by everything now in the Constitution, but that anything hereafter placed therein must be signed before it is binding.

DR. J. H. HOLLISTER, of Illinois, Chairman of the Section on Practical Medicine, then delivered

THE ADDRESS IN MEDICINE

briefly as follows:

"In the development of medical science men have been compelled to grapple with some of the most difficult problems which can arise for investigation. Unlike other pursuits, Medicine has to wend her way with steps slow, uncertain, sometimes in truth, oftimes in error, ever conscious of her weakness, and of the mysteries that surround her on every side.

The matters of life and health have been the subject of investigation by some of the greatest minds that have ever lived, but causes of disease are so complex that the best of minds have been compelled to rely largely for them on suppositions. In the absence of positive knowledge, no man can lay a restraining hand upon the fancies and credulities of man, and medicine has been unfortunately a fruitful field, above all others, for suggestions, but the treasure-house of both has been slowly but surely garnered with the fruitage of truth, and the ages spent so blend together in their enfoldings that each seems but a link in the continuous chain of progress.

During the past year the labors of scientific men have not been without fruit. First we may congratulate ourselves that the year has been so prolific of trustworthy and active labors. Perhaps no year in the world's story has been so marked by original investigation. No mind can now afford to shine with borrowed light. The present army of workers seem rather a galaxy of stars, differing, it is true, in magnitude, but each ready to contribute his share to the light of science, ready ever to repudiate everything that has not been verified, and as ready to criticise and reject where data are insufficient. Such a spirit is yet destined to attain results which could never otherwise be attained. There is also a spirit of union in the labor of all countries. Neither is Germany, France, or England regardless when Italy speaks, nor is any portion of the old world regardless when the new world utters her voice. Literature is also receiving a new impulse. New and efficient contributors are coming to the front. All departments are having fuller and abler expression of their work.

Of course, some curious deformities are among the results, and they are growing more conspicuous. Journals with conspicuous names and bodies of extremely diminutive size are floated, in which manufacturers of proprietary remedies assume to direct the medical profession how medical journals are to be run. But there will be a counter-movement some of these days, and when it does come this unprecedented nuisance will be abated.

The advancement of the day is best shown by the fact that physicians now read more, think better, and practice with better success. At no time were there better investigations being made. Pathological research and physical diagnosis have reached the point that has been heretofore never attained. More than in any year before have the centres of intensest study been

brought within the range of the microscope. In this new field, to which so many eyes are now turned, no man can longer speak as an authority who cannot with equal skill review the work of other men. Men yet differ vastly as to the interpretation of what they see, and new fields for investigation are being opened every day. Increased power has been given to the lens, so that the $\frac{1}{140000}$ of an inch and a fraction more is now within the limit of our vision. It is hard to say where the limits of human vision will fall in microscopy.

Two subjects demand more attention than any others at this time. One is the composition of the blood, and the other is the agency of microbes in blood. The third corpuscle in the blood has been described. It is now, by the way, pretty well established that Dr. Norris, of England, was its discoverer, and that the credit does not belong to Italy. Then some observers claim that a close reticular framework pervades every part of the blood-cell, while others say the reticulum depends upon defects in your lenses. Perfect these and the reticulum disappears; and I must confess I think the latter have the best ground.

Perhaps the most prominent man that confronts us is Robert Koch, formerly a little known practitioner, but now at the head of the Imperial Health Bureau of Berlin. His prominence is based upon his discovery of the bacillus tuberculosis. One very important question is:—Are these bacilli positive or concomitant? After numerous experiments by various observers, the proof remains very strong for accepting the germ theory of disease.

We now come to the question of the germicide treatment. The great question is not whether we can destroy bacteria, but whether the human organism will not first succumb to the agents used.

Dr. Hollister then spoke at some length of a more efficient means of elevating the standard of medical education. His plan is to have boards appointed, to be paid by the Government, who shall examine all applicants for the degree of M.D. Then in a few years let the State Boards of Health require that no one shall practise in the State who has not passed the examination of this board. The only opposition to this plan, he was confident, would be on the part of the few hundred professors in medical institutions, and if the measure were adopted, we should soon have none but the best schools remaining, while the standard of capability would be much elevated.

He also referred approvingly to a law recently passed in Italy, prohibiting the sale of any patented medicine until the ingredients were fully made known.

THE ADDRESS IN OBSTETRICS AND DISEASES OF WOMEN

by J. K. BARTLETT, M.D., of Wisconsin, Chairman of this Section, was then read, on account of impairment of the author's voice, by Dr. N. Senn, of Wisconsin.

The address dealt with the advancements recently made in operative gynecology, and the remarkable results thus obtained. He referred to how mere stitching of a lacerated cervix causes the most troublesome symptoms to immediately disappear. Bad results in Battey's operation have been obtained on account of the difficulty of making an accurate diagnosis in some cases of ovarian disease. He then referred to the recent discovery that many cases of vaginitis and other catarrhal conditions of the generative organs depend upon dropsy of the Fallopian tubes, caused in some cases by an antecedent pelvic peritonitis. Extra-uterine pregnancy, he said, is now robbed of its dangers, by destruction of the fœtus, in the early periods of gestation, by a galvanic current, not sufficient in strength, however, to cause rupture of the sac. The transfusion of blood, milk, and other nutritive fluids, of weak salt solutions, and of plain water were referred to, and good results in many cases reported. The author expressed the belief that the use of the forceps in the second stage of labor is becoming too common, and that many instructors encourage it. Referring to a new invention, by which a belt, passing around the waist of the accoucheur, is made to assist, he said, doubtless, in a few years, we will have an electro-motor engine of one-horse power invented, which will relieve the attendant, the mother, and the child, of any part in the procedure. The use of ergot in small doses during the second stage, he thought justifiable and proper in cases of uterine inertia, but full doses should not be given during labor: Lastly, he considered at length the subject of antisepsis.

THE COMMITTEE ON NECROLOGY,

DR. J. M. TONER, of Washington, Chairman, reported brief sketches of the lives of thirty-six members deceased since the last meeting.

The Nominating Committee then reported the following nominations of members of the

BOARD OF TRUSTEES OF THE JOURNAL,

to fill the positions occupied by those whose term expires this year, and one to fill the vacancy occasioned by the resignation of Dr. N. S. Davis: A. Garcelon, of Maine; J. O. Hooper, of Arkansas; L. S. McMurtry, of Kentucky; and J. H. Hollister, of Illinois.

THIRD DAY—JUNE 7TH.

GENERAL SESSION.

The Association was called to order at 9.30 A.M., and prayer was offered by the REV. DR. RULISON.

THE PRESIDENT announced that he had appointed

DELEGATES TO THE INTERNATIONAL MEDICAL CONGRESS,

to be held at Amsterdam, in 1883.

DR. KELLER, of Arkansas, called up his

AMENDMENT TO THE CONSTITUTION

offered last year, which provided that the designation of the time of the annual meeting shall be left to the Committee on Nominations, and not be limited, as heretofore to the first Tuesday in May or June. Adopted.

DR. BATCHELOR offered a resolution, which was adopted, that the President shall appoint one or more members from each State whose duty it shall be to secure by petition or otherwise the passage in their respective States, of more stringent laws respecting the

SALE OF POISONS.

DR. FOSTER PRATT, of Michigan, offered a resolution which had been adopted in the Section on State Medicine on the preceding day on the

DEATH OF DR. WM. FARR,

of England, wherein the Association recognized him as the founder and first tabulator of vital statistics, and placed on record its high appreciation of his services, and its deep regret at his death.

TRAINED NURSES.

DR. S. D. GROSS, of Philadelphia, offered a resolution, that in recognition of the necessity of trained nurses, and the benefit that has arisen from the establishment of training-schools for nurses in large cities, the Association recommends the establishment of similar schools in every county of each State, instruction to be given gratuitously, or at rates which would not exclude the poor from their benefits.

DR. WALTER HAY, of Illinois, moved that a special

SECTION OF PSYCHOLOGICAL MEDICINE

be organized. Laid over for one year, in accordance with the rules.

The report of the Standing Committee on

ATMOSPHERIC CONDITIONS AND THEIR RELATIONS TO THE PREVALENCE OF DISEASES,

was presented by DR. N. S. DAVIS, *Chairman*. He stated that the work of the Committee was begun as quickly as possible after the last meeting. Observers had been appointed in twelve different parts of the United States, who received instructions to take accurate observations, during the day and night, of every day in the year, as well as to note the presence of any organic matter in the air. He then spoke of the necessity of continuing the observations through several years, and closed with a statement of the finances of the Committee.

The resolution offered by DR. DIDAMA, on the first day, for the taking of

CLIMATIC OBSERVATIONS

at the general health resorts and watering places, was then adopted.

DR. N. S. DAVIS, of Illinois, moved that Dr. Didama be elected the committee to carry out the objects of the above resolution. Adopted.

REVISION OF THE CODE OF ETHICS.

DR. S. POLLAK, of Missouri, offered a resolution on behalf of the St. Louis Medical Society, to the effect that whereas many of the provisions of the present Code of Ethics are obsolete, and that early revision is necessary, and no Society except the American Medical Association has any power to alter the present Code, but only to ask for its revision; therefore, that the American Medical Association be respectfully requested to appoint a committee of one member from each State, for the purpose of taking into consideration the propriety of revision of the Code of Ethics of the American Medical Association, and report thereon at the meeting of 1884. That this committee be authorized to propose a Code of Ethics, which in their opinion will meet the wishes of the profession, and to submit the same at the next annual meeting.

It was immediately moved and seconded by more than a hundred voices that these resolutions be laid upon the table, and the motion was carried almost unanimously, amidst loud applause.

THE READING OF PAPERS IN THE SECTIONS.

Dr. William Brodie, of Michigan, offered a resolution that no paper should be read in any of the Sections before it had received the approval of the Secretary of that Section. Laid on the table.

THE ADDRESS IN SURGERY

was then read by W. F. PECK, M. D., of Davenport, Iowa:

In performing the duties of Chairman of the Surgical Section, it is not deemed practicable to encompass all that the organic law of the Association may contemplate. For, in reporting on the progress made in surgical science, it is recognized that many theories are at present announced as facts which, when experience and demonstration shall have thoroughly tested, may be eliminated, to perhaps appear when the cycle of professional experience again completes its revolution. The greatest progress has been made in operative surgery, although other departments have been constantly endeavoring to add new light and obtain results to our already extensive accumulations. It is not claimed that large numbers of new operations have been originated and performed, but it is evident that the better understanding of pathological conditions has stimulated surgeons to establish a standard for operations hitherto ventured in rare and extreme instances. In Pathology, the microscopist has been active in trying to define and locate the germ cause of disease, since Cohnheim gave to the profession in a complete and formulated manner the character and importance of the colorless corpuscle in pathological changes. Strenuous efforts have been put forth by Pasteur, Koch, and others to unfold the importance of the bacterian germ which, according to the demonstrations of some well-known authorities, have a normal existence in the blood, lymph, and tissues of the body. Burdon Sanderson, Chauveau, Watson Cheyne, Billroth, and many others have adduced much information which certainly cannot do otherwise than benefit, even though a great modification of the bacterian theory is made necessary. Certain it is that during the year there has been developed a strong feeling in favor of Koch's views concerning the bacilli and their alleged tubercular relations. That these micro-germs exist there can be no longer any doubt. But whether they are the cause of the tubercle, or whether the tubercle develops *them*, their study has not made sufficient progress as yet to justify an unequivocal statement. In Prussia there is existing, under the leadership of Koch, a strong belief in favor of the bacilli being the cause of the deposit; while in Austria, Spina leads the opinion that the bacilli are produced *by* the tubercle, *or*, the associated conditions which originate the tubercular matter. If the following statement of Spina be true, then there is much uncertainty surrounding the whole theory of bacilli being the cause of tubercle: "I have examined about one hundred and fifty mesenteric and omental tubercle in the most various stages of their development, according to Koch's and Ehrlich's method, and found bacilli in *not one* case."

The surgeon is much interested in these investigations because of the important statements made by eminent teachers concerning the origin and nature of some forms of articular disease, also the peculiar degeneration which takes place in bone and glandular structures. The interest does not stop with these tissues, for underneath it all the "germ theory," which is thought by many excellent men to be the greatest of all causes in engendering infectious inflammations, pyæmia, septicæmia, abscess, gangrene, etc. etc., receives a support which, if conceded, will tend to give new and more efficient reasons for the use of antiseptic ism in practice. Now that so many able and relentless workers are seeking information which promises greater accuracy, it may be well to not claim too much for remedies which are given with the expectation that they shall ultimately reach the habitation of the noxious germ and there hold mortal combat, and win the victory, for further life in tissue which is threatened with decay and death. It cannot be admitted that practical surgery has thus far been directly benefited by Koch's views.

The condition of the problem of the management of wounds and other pathological processes by means of the so-called antiseptic methods suggests a move in the direction of greater confidence in the details of operative procedure, and scrutinizing attention in extreme cleanliness in the minutiæ of practice.

It is difficult, in fact impossible, to state with precision the exact deviation in the direction of, for or against, treatment of wounds by the different chemical agents during the past year. With many, the custom is to believe that antiseptic practice in surgery means the application of *carbolic acid*, in some form of attenuation, to the cut or exposed suppurating surface. Different surgeons have used different substances, but,

according to the experience of Dr. A. T. Cabot, of Boston, upon detached dead tissue, it was found that carbolic acid acted more promptly than any other agent in arresting putrefaction and destroying micro-organisms connected with the changes of decomposition.

Within the year the antiseptic methods of wound manipulation have been regarded as embracing the spray, fixed and intimate relations of fresh surfaces, rest, pure air surroundings, and, when practicable, drainage.

It was stated by Thornton that the principal danger which surrounded opening of the abdomen was from the action of the vicious bacteria. And Spencer Wells' unprecedented (!) experience in ovariotomy is referred to by Marcy as furnishing almost incontrovertible evidence in favor of the antiseptic practice.

In this connection the experience of Mr. Lawson Tait, who reports one hundred successful ovariotomies with but three deaths (none of the antiseptic precautions having been regarded), should also be remembered by those who can only see progress and success in treating wounds on an anti-germ plan. Certainly the new experience of Billroth and Esmarch is commendable, and should be gratifying to those eminent operators. But it cannot be successfully argued that the lessened mortality was alone due to the use of antisepticism as practised by Lister. It will be immediately asked, how else can these alleged great changes in practice be explained, if everything that is used to keep a wound clean and to insure thorough drainage is called antiseptic practice? then no adequate explanation can be offered. Is not the experience of Mr. Keith as wonderful as the tabulations of the Vienna and Kiel surgeons?

The experience of the English surgeons on duty with the British troops in Africa, during the Zulu and Transvaal wars, was such that the antiseptic management of wounds was commented upon with but little favor after the records of those campaigns were finally submitted. The rather short campaign in Egypt was characterized by great dissatisfaction in the beginning of the war, but after the surgical management had become thoroughly organized and freed from abuses, observations were made by good men, who had only good reports to make of the antiseptic practice, which was very generally employed. While it is admitted that most of the leading surgeons of England are thoroughly wedded to the practice of antiseptic treatment of wounds, there are to be found not a few excellent teachers and operators who most reverently believe that nature, under wise assistance from the surgeon, will do more to save limb and life than the surgeon can do, who depends upon restricted antisepticism. The speaker has opened the abdomen in all forty-eight times; in forty-six instances for the removal of ovarian growths, once for an adherent ovary, and once for an intestinal obstruction. In the first fifteen cases there were six deaths. The operations were made under the spray, and the wounds were treated with a carbolic-acid solution. In the remaining thirty-one ovarian operations, also in the oöphorectomy and in the case of laparotomy, the spray was not employed. The last two mentioned cases recovered, and out of the ovariotomies there were four deaths. Has it occurred to those who are strong in their advocacy of the antiseptic treatment of wounds, that in the United States there are in active practice among the 52,000,000 of inhabitants about 86,000 medical men, a very large number of whom are treating wounds and pathological lesions? Also that many of the wonderful results accomplished by these numerous surgeons are wrought not by means of the spray and carbolic acid, but by the extraordinary care and attention which are given their cases.

Those who report their results in the periodicals are unfortunately few. Major operations are performed in apparently out-of-the-way places, and their results thus lost.

After referring to several new instruments, and the application of the electric light, the speaker referred to the legitimacy of bloodletting in inflammation.

Among the comparatively new operations, gastrostomy and laparatomy were fully referred to, and the details of several cases in practice were given. Referring to the results of these operations, the speaker asks: If the cancer, the cause of these operations, be due to a general cause, can the surgeon expect the patient to receive more than temporary relief from the operation? Will the aggregate life in successful cases be greater than those who die as the direct result of the disease? Experience has shown that after operative procedure, the aggregate life *is* longer than if the disease were left without treatment. Referring to neoplasms, the speaker stated that the venerable and universally honored Gross gave, in a paper before the late meeting of the American Surgical Association, the opinion that neoplastic additions to all tissues are the sequence of a previous injury. While perhaps this view is not original with the author, it is nevertheless an opinion of great value, coming, as it does, from an experience so ripe and comprehensive.

Professor Pietro Loreta's operations for stenosis of the pylorus, by stretching the stricture with the fingers, has resulted in two recoveries out of four operations, Dr. David Newman, of Glasgow, has performed the operation of nephrorrhaphy, it being the first operation made in England upon a woman for floating kidney; the renal capsule was stitched to the margins of the incision, and deep button-sutures were passed through the kidney substance, thus fixing the organ in its natural position. The patient recovered.

Dr. A. E. Baker's new operation for varicocele consists in separating the veins of the cord from the vas deferens, and then passing a needle threaded with twisted silk behind the veins, after which the veins are permitted to drop back when the needle is returned in front of the veins, which are thus secured in the loop of the ligature, through the original opening. The thread is then made tense, and the veins are brought close to the wall of the scrotum, and the ligature is well tied, cut close to the knot, and then allowed to return with the veins to the scrotal cavity. The results are such as to commend a further trial of the operation.

Important additions have been made to our surgical literature in monographs, revised editions of some of the leading text-books, and in America, the profession may be congratulated upon the appearance of two important volumes—one on anatomy and one on surgery. In the *Medical and Surgical History of the War* the world is now in possession of the most complete record of wounds and injuries resulting from war and battle that has ever been produced. Dr. Harrison Allen, of Philadelphia, has produced the major part of what promises to be when completed an excellent treatise on human anatomy, including its medical and surgical relations.

DR. FOSTER PRATT, *Chairman* of the Section, then delivered the

ADDRESS ON STATE MEDICINE.

He said that psychology, medical jurisprudence, and medical expert testimony have each received, during the past year, the attention to which they are entitled, but that there has been no noteworthy advance in any of these departments. Not more than fifteen years have passed since sanitary work was begun in the United States. Our advance may seem slow; but to-

day, as we remember the advanced work of 1883, as compared with the beginnings of 1873, we must congratulate ourselves that so much has been done.

In reply to the question, What had been accomplished by sanitary science? he stated that sanitary organization and sanitary machinery have been largely developed. Sanitary conventions, societies, books, lectures, and discussions have gradually multiplied, clearly indicating an appreciation of the work, and a desire for more knowledge on the subject. The heating, lighting, and ventilation of our homes and other buildings have been improved; the influences which vitiate the air have been removed, or methods for their neutralization adopted. The causes of disease we find to depend largely upon fixed physical laws, and by the discovery of these we are able to prevent disease. In twenty-nine States sanitary organizations have been adopted, while eleven still refuse to make any provision for a State Board of Health, but ere long every State in the Union will fall into the line of advancement, and then a majority of States will demand a National Board of Health. What then will Congress do?

The isolation of contagious diseases has done much to prevent their spread. Dr. Pratt then referred to the admirable work done by the late Dr. Farr, of England, in originating the work of collecting vital statistics. He then gave a description of advanced methods of work in his own State, and including sanitary meetings at which papers on sanitary questions were read, by physicians, ministers, dentists, and ladies. He said that we owe much of our advancement to ladies. (Applause.) By recent improvements in sanitary science five per cent. has been added to male and eight per cent. to female life. Finally he insisted on the importance of careful isolation of all cases of all contagious diseases.

THE REPORTS OF THE TREASURER AND LIBRARIAN

were then read and accepted.

THE COMMITTEE OF PUBLICATION

reported that an index of all the volumes of Transactions was now in preparation, of which 1,500 copies would be issued, at a cost of $500, and would be sold to members at one dollar per volume. The report was received and adopted.

THE COMMITTEE ON NOMINATIONS

presented the following report, which was adopted:

President.—AUSTIN FLINT, SR., M.D., of New York.

Vice-Presidents.—R. A. KINLOCH, M.D., of Charleston, S. C.;

T. B. LESTER, M.D., of Kansas City, Mo.;

A. L. GIHON, M.D., of U. S. Navy; and

S. C. GORDON, M.D., of Portland, Maine.

Treasurer.—R. J. DUNGLISON, M.D., of Pa.

Librarian.—C. H. A. KLEINSCHMIDT, M.D., of Washington, D. C.

Place and Time of Meeting.—Washington, on the first Tuesday in May, 1884.

Chairman of Committee of Arrangements, A. Y. P. GARNETT, M.D., of Washington.

Assistant Secretary, D. W. PRENTISS, M.D., of Washington.

CHAIRMEN OF SECTIONS.

Practice of Medicine.—J. V. Shoemaker, of Pennsylvania.

Obstetrics.—T. A. Reamy, of Cincinnati.

Surgery.—C. T. Parks, of Illinois.

Ophthalmology.—J. J. Chisolm, of Baltimore.

Diseases of Children.—Wm. Lee, of Indiana.

State Medicine.—J. D. Roberts, of Tennessee.

Oral Surgery.—T. W. Brophy, of Illinois.

OHIO STATE MEDICAL SOCIETY.

Annual Meeting, held at Cleveland, June 5, 1883.

(Specially reported for THE MEDICAL NEWS.)

THE Ohio State Medical Society met at Frohsinn Hall, Cleveland, at 9.30 A.M., June 5, THE PRESIDENT, DR. LANDON, in the chair.

The address of welcome was delivered by Dr. A. C. Miller, of Cleveland.

The Committee of Arrangements, by its Chairman, Dr. R. A. Vance, of Cleveland, presented the following report, which was adopted:

The Committee of Arrangements recommend—

1. That a Committee be appointed to act in the absence of the Society. Thus members can pay up their dues, and applicants for membership file their papers, and all become members of the American Medical Association.

2. That the Society adjourn for one year, the old officers to hold over.

3. That we then adjourn.

On motion of DR. R. A. VANCE, it was voted that the President be permitted to publish his Annual Address.

On motion of DR. E. H. HYATT, it was voted that the Society meet at Columbus one year from date.

THE PRESIDENT appointed Drs. G. A. Collamore, W. B. Scranton, and E. H. Hyatt members of a committee to represent the Society.

On motion of DR. J. F. BALDWIN, the vote to hold the next meeting one year from date was reconsidered, and the committee just named was empowered to fix the date of next meeting.

On motion of DR. J. F. BALDWIN, amended by DR. J. W. RUSSELL, it was voted that no assessments be made for the next year, and that applicants for membership apply at once to the Committee on Admissions.

THE PRESIDENT appointed Dr. A. N. Reed *vice* Dr. W. H. Mussey, deceased, and Dr. J. O. Dawson, *vice* J. B. Thompson, absent, as members of the *Committee on Admissions.*

Adjourned.

AMERICAN SURGICAL ASSOCIATION.

Fourth Annual Session, held in Cincinnati, May 31, and June 1 and 2, 1883.

(Specially reported for THE MEDICAL NEWS.)

FIRST DAY, MAY 31ST.—MORNING SESSION.

THE PRESIDENT, SAMUEL D. GROSS, M.D., LL.D., D.C.L., called the Association to order at ten o'clock, and opened the proceedings with the following

ADDRESS:

Allow me, as your presiding officer, to congratulate you upon your safe arrival, and to extend to you a cordial welcome to the "Queen City," the centre of medical education in the "Buckeye State," the residence of eminent medical teachers and practitioners, and the repository of the ashes of great medical men, who, during their laborious lives, added lustre to the profession, and left behind them undying names.

We have come hither, not as pleasure-seekers, but as members of a great body of men bent upon earnest work in the interests of our great and noble calling. It is a source of rejoicing to me, as I am sure it is to you, that since our last meeting our ranks have not been invaded by the "Fell Destroyer." On that occasion it was my melancholy duty to announce to you the demise of four of our Fellows, all men of distinction, and of great usefulness. The meeting upon which we are about to enter cannot fail, if we may judge from our programme, to be one of unusual in-

terest, and that our deliberations will be conducted with the celerity and harmony of feeling which have hitherto characterized it, I am safe in predicting. Allow me, in concluding this brief salutatory, to direct your attention to a proposed alteration of the constitution, to increase the number of Fellows from one hundred to one hundred and fifty. The change is an important one, and merits our serious consideration. I also respectfully suggest that the acting Council be increased from four to seven, so as to impart greater efficiency to its work. Finally, it appears to me wise to take action upon any proposed amendments of the constitution and by-laws on the last day of every session, instead of letting them lie over for one year, as now provided for.

Dr. P. S. Conner, *Chairman of the Local Committee*, next addressed a few words of welcome. He said:

Mr. President and Gentlemen of the Association: It is with pleasure that we welcome you to Cincinnati. We are exceedingly grateful, not only to have you come to our city, but to have so many of you with us. The Committee trusts that you may find things arranged with satisfaction, so far as the times of meeting, the order of the proceedings, and other appointments are concerned, and we desire that you may notify us of anything that is not satisfactory. We have only to hope that you may, in going from us, carry away with you as pleasing remembrances of the meeting, as we shall ever have of seeing you here.

GENERAL BUSINESS.

The Secretary, Dr. J. R. Weist, then read the minutes of the last meeting, which were adopted.

It was ordered that an additional member be added to the acting Council, and the President appointed Prof. E. M. Moore, of Rochester, New York.

THE TREASURER'S REPORT

was read by Dr. John H. Packard. It showed a deposit to the credit of the Association of $2,270.31.

The Council was instructed to take action on the applications for membership, there being now eleven vacancies.

The Secretary then read a communication from Dr. Willard Parker, of New York, accepting his election to membership in the Association

Dr. C. B. Nancrede, of Philadelphia, then read the first paper. His subject was

HAVE WE ANY THERAPEUTIC MEANS, AS PROVEN BY EXPERIMENT, WHICH DIRECTLY AFFECT THE LOCAL PROCESSES OF INFLAMMATION?

He said that, owing to the press of circumstances, he would limit his paper to the consideration of the early stages of inflammation. Careful study of the essential processes of various morbid conditions has often led to the theoretical employment of therapeutic measures, which by their apparent usefulness have encouraged their future employment. But if, in addition, we find that our *a priori* therapeutics, when experimentally applied in the case of animals, actually produce the precise effects we have theoretically aimed at, we can hardly go astray in confidently applying similar treatment to the human subject.

This paper is avowedly written in advocacy of bloodletting in general, but chiefly of the local abstraction of blood, for the pendulum of unreasoning prejudice and authority is now swinging slowly back to the opposite point.

He then reviewed briefly the minute processes of the earlier stages of inflammation.

Whether or not a primary contraction of the arteries occurs depends largely upon the irritant used. Certain it is that, at an early period, the arteries, normally one-sixth the size of the veins, far exceed them in size. The circulation is accelerated in the dilated vessels: the rate soon becomes normal, then slows, then an oscillatory motion occurs, a temporary stagnation, again a resumption of the flow, and finally permanent stasis. The obstruction consists entirely of red cells, closely packed. Free diapedesis of the white corpuscles then occurs from the excess of oxygen. That the primary acceleration of the blood-stream is in some way dependent on reflex nerve action seems clear.

A physiological point or two must be here considered. Ranvier shows us that the white blood-corpuscles become sluggish in the absence of oxygen, and *vice versa*. The red cells carry the oxygen. In stagnation of these, then, we must have an increased amœboid movement of the white cells and consequent migration. The author concluded, therefore, that a theoretically perfect remedy for incipient inflammation must comprehend the following effects:

It must lessen the vis-a-tergo; it must prevent such an ingress of blood into the affected part as will increase the quantity of oxygen; or it must so lessen the difficulty of escape on the venous side that a ready drainage of venous blood may occur. If possible, both results must occur, *i. e.*, increased frequency, with decreased force of the heart's action.

In his experiments of the frog's tongue, the first effect of localized bloodletting from a large vein on the distal side of a wound was an oscillation of blood-disks, then an occasional momentary flow, then suddenly a rapid resumption of the circulation.

All that was now needed was a corroboration of the results of Gensmer, who observed that the capillaries, after free bloodletting in an inflamed part, rapidly returned to their normal condition. He considers the antiphlogistic effect of local bloodletting due to a purely mechanical cause.

The effect of general bleeding, is to increase the water relatively, and decrease the red corpuscles of the blood; an increased rapidity with decreased force of the heart's action; this by relieving intravascular pressure, stasis, etc., prevents diapedesis of cells and exudation of blood-plasma.

But how about the evil effects of bloodletting? It is well known to the older practitioners that these are only temporary and easily repaired. For best results we should open a vein leading from the inflamed focus.

The author then summarized his views as follows:

1. During the stage of dilated arteries with increased rapidity of current, little danger of capillary changes need be apprehended. Here ergot, and perhaps arterial sedatives are useful.

2. After stasis, weakening of heart's action can do nothing.

3. The object desired is a removal of obstruction, diminution of force, increase of rapidity.

4. Arterial sedatives in the later stages are usually inadmissible, except as succedanea of bloodletting.

The discussion on this paper was spirited, and disclosed much difference of opinion. It was opened by Dr. H. F. Campbell, of Augusta, Georgia, who said that the "lost art," as bloodletting was characterized by our worthy President a few years ago, has for a number of years grown more and more into disfavor, until now it is almost a disgrace to us to bleed under any circumstances; and even local bloodletting has been laid aside. I do not bleed as much as I used to do, but as a professor of surgery in a university, I teach my students the use of the lancet, as carefully as I teach them the use of the knife, in cutting for stone or in any of the more brilliant operations.

We do not know all the conditions of inflammation. They are better described than defined. The conditions of heat, pain, redness, and swelling were recog-

nized long ago, but now we recognize them as the symptoms of true inflammatory action due to the presence of too much blood in the part. What benefit is there in incision, cupping, leeches, and the application of cold, but to drive the blood out of the part? We put on a bandage and elevate the limb, in order to drain away the blood. All our practices are based on the one idea of too much blood in the part.

PROF. MOORE, of Rochester, N. Y., said that one great hindrance in the way of our using the lancet properly is the great difficulty in many cases of making a proper diagnosis.

He then related an epidemic of pneumonia which had, a good many years ago, occurred in his neighborhood. In it every patient was bled, and every patient without exception died, until in a consultation he proposed a change. He said, "let me stimulate instead of bleed." It was done, and at once the result was changed. He also related another epidemic of cerebro-spinal meningitis, in the early part of which the patients were all bled and all died. But a change was made, and quinine and stimulants employed, and the patients recovered. When this result was related to him, he expressed surprise and an incredulity as to the diagnosis. He was soon after called upon to make a post-mortem examination, when he found the spinal cord and brain bathed in pus. He at once profited by the experience, and was rewarded by seeing his patients recover.

PROF. POST, of New York, remarked that there are certain conditions with regard to inflammation in its very early stages that it is well for us to consider. One of the chief of these is the influence of position in hindering the access of arterial blood and in favoring the return of venous blood from the part. Practitioners are well acquainted with the importance of this. We cannot attach too much importance to gravity in the treatment of inflammation. Another important improvement in the early treatment is that of making equalized pressure on the part by bandaging, thus keeping the veins empty. He agreed with the author of the paper that bloodletting in the early stages of inflammation is of the greatest importance, provided there is no asthenic condition forbidding it.

He then related the history of a case in the Presbyterian Hospital, New York, whose head was injured. The patient was in a delirious state, so violent that he had to be bound. He was bled; the delirium vanished for three days, when the same remedy again gave relief. He then spoke of the action of bloodletting upon the puerperal condition, stating that it quieted the delirium, and that during the sleep which ensued, the disease was broken.

DR. KINLOCH, of Charleston, S. C., agreed with the statement that bloodletting is a great remedy for inflammation, but he admitted that it had often proved unsatisfactory in his hands. While local bloodletting abstracts blood from the part, it is doubtful whether it lessens the inflammation.

PROF. GUNN, of Chicago, asked attention to the fact that there is great difference between traumatic inflammation and inflammation due to other causes. There are undoubtedly cases of traumatic inflammation and of inflammation of the brain—a condition known as apoplexy, which has been greatly benefited by bloodletting.

PROF. BRIGGS, of Nashville, Tenn., agreed that there are conditions which call for bloodletting—cases of young, robust individuals with good habits. Bloodletting in such cases is a remedy yielding results which no other remedy will yield; but if it is not performed at the proper time, or in the proper manner, it is useless.

PROF. GREGORY, of St. Louis, stated his belief in bloodletting as one of the most rational means of treating inflammation. No one can dispute that we have in an inflamed part a local blood-pressure. Certainly, the most rational treatment of this is to take blood directly from this part. So far as we know of inflammation experimentally, it has but one object—that of repair—and as a rule, inflammations are advantageous, but we must endeavor to regulate them.

PROF. W. W. DAWSON, of Cincinnati, asked: If this is such a very great remedy, why have we abandoned it? Does the gentleman who so earnestly advocated its use bleed a patient once a year? I venture to say he does not.

DR. NANCREDE, in closing the discussion, called attention to a few points upon which his meaning had, to some extent, been mistaken; and he remarked also that we are too much afraid of the loss of the red blood-cells, and forget that their loss is so quickly replaced.

DR. B. A. WATSON, of Jersey City, N. J., then read a paper on

LISTER'S SYSTEM OF ASEPTIC WOUND-TREATMENT VERSUS ITS MODIFICATIONS.

Lister's treatment of wounds aims to secure the following conditions:

1. The continued exclusion from wounds of all living germs, or the prompt destruction of the same where they have gained admission, thus preserving in the wound a perfectly aseptic condition until it has healed.

2. Complete and uninterrupted approximation of the wound surfaces.

3. The avoidance of all irritation or any disturbance of the relation of the wounded parts.

Now does the Lister system fulfil these indications? He thought it must be admitted that it is possible to render *completely aseptic* nearly all wounds, and to preserve them in this condition during the reparative process by the means employed in the Lister treatment. Lister's is not an empirical method, but a complete system of practice based on scientific principles and facts, in which respect it differs to-day from all its so-called "modifications."

The value of this system of wound-treatment is shown by the fact that the old methods are no longer employed, except when modified or improved by engrafting upon them certain parts of the Lister treatment. In some instances, these modified forms of treatment aim to differ but little from the original, and are, as a rule, with the exception, perhaps, of the poultice dressing of Mr. Savory, based upon the principle of interference with the growth and fermentive action of bacteria.

The Listerian system is opposed entirely by those who have never practised it. Their chief argument against the practice appears to be based on the fact that in some instances organisms have been found under the so-called Lister dressing. The finding of these organisms has been often questioned, but never absolutely disproved. It may now, however, be boldly asserted that if they are found under these circumstances, they have certainly lost their power to produce septic infection. It is true, Mr. Keith and a few others have expressed a want of faith in the efficacy of the spray, while others prefer irrigation. The efficacy of the latter procedure cannot be questioned by those who admit the germicidal property of the carbolic acid solution of sufficient strength. But does not the spray deposit a continuous layer of the solution, rendering it impossible for germs to reach the wound without passing through the wet line, which is fatal to them? Is it not in fact irrigation?

We now come to the modifications: Dr. T. M. Markoe, while he shows himself satisfied with the results of the Lister treatment, prefers a modification

of it. His plan, he tells us, consists "In the free and constant use of appropriate solutions of carbolic acid in water, no care being taken to keep the wound shut off from the influence of the atmosphere." He evidently aims his present efforts against the application of the germ theory to the treatment of wounds. But is not Dr. Markoe's theory of the action of carbolic acid exploded? The acid does exert a restraining influence on inflammation, but it neither prevents nor arrests it. I have examined, from these standpoints, not only Markoe's modification, but the most of those which have been proposed, and am now fully prepared to assent to the statement of Dr. J. Lucas Championniere, that "Perchance, in exceptionally favorable conditions, one may omit some parts of the dressing . . . but the *ensemble* of the method must remain," and "I assert more emphatically than ever that we can do no better than to remain faithful to the words of the master."

DR. JNO. H. PACKARD, of Philadelphia, stated that if he had correctly understood the essayist to state that the majority of surgeons in the United States are adherents to the Lister system, he must speak for the surgeons of Philadelphia, for, so far as he knew, none of them ever practised it. He believed they dragged on a miserable existence without it, but got along very well.

DR. POST made a similar statement in regard to the surgeons of New York.

DR. VANDERVEER stated that none of the surgeons of Albany or vicinity employed the system. He believed that thorough drainage was the important part of treatment.

DR. NANCREDE stated that he had returned to Listerism.

DR. CAMPBELL believed that carbolic acid retarded the process of inflammation through its action in retarding reflex nervous irritability rather than by its antiseptic powers.

DR. RICHARDSON, of New Orleans, stated that there is not a surgeon in his State who uses the Lister method.

DR. MCGRAW, of Detroit, related the case of a child that he had lost from the use of a two per cent. solution of carbolic acid.

DR. MASTIN, of Mobile, stated that the surgeons of Alabama never use the Lister method.

DR. PRINCE, of Illinois, said we could not be too thankful to Mr. Lister for calling attention to the importance of avoiding the contact of wounds with those agents which we know float in the air. The Lister system in detail, he considered too complicated. "If Listerism means the details of the process of dressing wounds, it is short-lived; if it means the principles involved, then it is immortal."

PROF. DAWSON, of Cincinnati, said that the great benefit we have derived from Mr. Lister's system is in its teaching us to enforce cleanliness. He doubted if we have gotten much of value from the practice of his methods; but he believed a great deal is due to Dr. Markoe in calling our attention to the importance of through and thorough drainage.

DR. WATSON remarked, in closing the discussion, that the gentlemen of the Association had shown the same willingness to misconstrue his statements that they had shown to the principles of the Listerian system. He had not stated that surgeons of the United States generally advocate the methods of Lister, but that the present surgical practice has been greatly modified by his principles.

AFTERNOON SESSION.

The first business of the afternoon session was the report of the Council on admissions. Eleven names were reported to fill vacancies. On motion, the balloting was deferred until to-morrow morning.

DR. JOHN H. PACKARD, of Philadelphia, then reported a case of

REAMPUTATION AT THE HIP-JOINT FOR OSTEO-MYELITIS.

On the sixth day hemorrhage took place, which was not controlled by pressure over the external iliac artery at the pelvic brim. The common iliac artery was therefore tied, and the patient recovered, the ligature separating on the twentieth day.

In connection with this case, a very similar one was mentioned, which occurred to Dr. Packard at the Beverly U. S. A. Hospital, in the winter of 1864–65.

Dr. Packard presented a "detached artery-needle," to be grasped with forceps; and made remarks upon the subject of ligation of arteries, and especially upon that of the common iliac. He also submitted a table embracing all the hitherto reported cases of ligation of this vessel not included in the tables already published.

DR. FIFIELD, of Boston, Mass., in opening the discussion, remarked that he did not doubt the very great skill and courage of Dr. Packard, displayed in this operation, but that if he understood the operation of Mr. Furneaux Jordan, he did not see the necessity for tying the common femoral or the abdominal trunk. He thought that all this might have been dispensed with in the one operation of Furneaux Jordan. He also stated that the old teachers of France taught their students to put the ligature around arteries by the sense of touch, with the eyes turned toward heaven.

DR. POST asked how we are to distinguish between the artery and vein by touch.

DR. CONNER, of Cincinnati, stated that he believed there are cases in which a modification of the operation of Furneaux Jordan does well, and he related a case which he had operated upon two years ago. In that case he had amputated at the junction of the middle and upper third of the thigh with the aid of Esmarch's bandage, and finding the condition of the medulla such as not to justify his leaving the bone, he made the lateral incision, having hemorrhage controlled by pressure, turned out the bone, tied the artery, and the patient recovered.

DR. PACKARD stated that his reason for ligating the femoral was that the idea of hemorrhage had occurred to him and he thought that was the safest means of avoiding it. The secondary hemorrhage did not come, as had been suggested, from the ligation of the femoral, but from a vessel deep down in the posterior flap, which he could not reach without endangering the femoral. He therefore, in the haste of the moment, ligated the primitive iliac, and had this ligature given way, he would have nevertheless done all that was in his power for his patient.

DR. RICHARDSON, of New Orleans, then read his paper on

ESMARCH'S BANDAGE APPLIED TO TRAUMATIC ANEURISM.

The paper was confined almost exclusively to the narration of a case, the important points of which were as follows: The patient received a shot-wound in the leg in October, 1876, followed by no serious hemorrhage. Eighteen months after, a tumor was observed. One year later, Esmarch's bandage was applied from the foot up to and beyond the tumor without, however, involving the tumor. This treatment failed, and the artery was ligated in July, 1879. Nearly eighteen months after ligation (Dec. 1881), thrombosis occurred and was followed by gangrene, necessitating amputation. Death occurred on the fourteenth day.

Dissection revealed an expansion of the artery to

form the tumor. It was also discovered that ligation had failed to produce coagulation. There was no communication between the sac and the artery below. The arteries higher up had undergone no change. The femoral vein was smaller than usual and its walls were very much thickened. It was closely connected with the tumor, indeed, absolutely continuous with it, communicating with it by a well-defined orifice. It was occupied throughout by a firm clot.

The specimens exhibited by Dr. Richardson were referred to a special committee, consisting of Drs. Nancrede, Kinloch, and Dawson, and the discussion was postponed until the morning of the second day's session.

DR. RICHARDSON then read a second paper on

THE USE OF THE TREPHINE IN TRAUMATIC EMPYEMA ASSOCIATED WITH THORACIC FISTULA.

Chronic suppurative pleuritis with an imperfect fistulous outlet, external or bronchial, is not an uncommon result of gunshot or other penetrating wounds of the thorax. The resources of surgery have hitherto not offered much encouragement to the sufferers. The main difficulties encountered are—1st, Imperfect drainage, due chiefly to the approximation of the ribs, caused by the "sinking in" of the chest-walls. 2d, Permanent separation of the lung from the chest-wall by the contraction of false membrane upon its surface. The best method of effecting drainage is, then, what we seek. The effort to make an opening through one or more intercostal spaces, has been shown to be impracticable. The idea of trepanning or trephining the thorax is not new. It is said to have been proposed by Hippocrates, and in later times modified by others in idiopathic empyema.

The benefits derived from resection are threefold. 1. Unobstructed drainage. 2. Free scope for application of antiseptic remedies. 3. Shrinkage of the chest.

In cases where the pus is confined to the lower and lateral regions, the best method is the application of the trephine at or below the fistula. This method, as well as he could ascertain, originated in New Orleans, where it has since been frequently employed.

The author then narrated several cases in which the trephine was employed with good results.

DR. PRUITT, of St. Louis, related a case which had come under his care a few years ago. A woman with an opening in the thorax from an old empyema came to him complaining of fever and cough; her general health impaired. It was evident that drainage was not sufficient. He enlarged the opening. She improved at once. In a few months, she came back with the same symptoms as before. Pressure on the drainage-tube had, as Dr. Richardson has pointed out, narrowed its calibre. He again enlarged the opening; but some time after, a sudden change occurred, which he was at a loss to explain. During the dressing of the wound, while the cavity was being washed out with a weak solution of carbolic acid, she suddenly complained of pain, became comatose and pulseless. From that time on, all manipulation of the wound occasioned so great pain and difficulty of respiration that treatment had to be abandoned. Ulceration had doubtless occurred, and in all probability pus had entered the mediastinum.

DR. MEARS, of Philadelphia, called attention to his method of introducing a large tube into the cavity, where there was sufficient space between the ribs, by means of a large hernial needle. The needle, its eye armed with the drainage-tube was passed through an opening in an intercostal space, then carried down and out at a similar opening two spaces below. He had used the method in the case of a child eight years old and in a man of thirty-two.

DR. CAMPBELL thought that the trephine would be a difficult instrument to use in these cases, and expressed the belief that Hey's saw would be preferable.

DR. RICHARDSON explained that the trephine cut through very quickly on account of the softness of the rib, and that in its use the difficulty of holding the rib in position, that is always encountered in the application of the saw, is avoided.

The Association then adjourned to the amphitheatre of the Ohio Medical College to witness the demonstration, on the dead subject, of the operation reported by Dr. Packard.

SECOND DAY, JUNE 1ST.—MORNING SESSION.

The Association went into private executive session for the purpose of holding an

ELECTION OF FELLOWS.

The result was the election of Dr. N. P. Dandridge, of Cincinnati, O.; Dr. Christopher Fenger, of Chicago, Ill.; Dr. W. E. Taylor, of California; Dr. W. F. Peck, of Davenport, Iowa; and Dr. McCamm, of Pittsburg, Pa.

DR. S. D. GROSS then read a paper on

THE VALUE OF EARLY AND LATE OPERATIONS IN SURGERY.

(See page 643.)

PROF. POST, of New York, expressed much pleasure at the excellence of this paper, and remarked that there was one point in it which above all others merited the consideration of the Association, and that was the importance of removing early a large class of growths, such, for example, as warts, which are in themselves harmless, but are nevertheless exceedingly liable to undergo various degenerations, or even become malignant.

DR. GREGORY, of St. Louis, agreed with most of its conclusions. With regard to the propriety of an early operation in cases of malignant growths there could be no question. He then entered briefly into the pathology of the sarcoma and carcinoma. He said that, as we look through the microscope at the awkwardly shaped cells of a sarcoma, or at those large cells of a cancer, enclosed in their rough matrix, we could hardly conceive of their ever being carried away from their situation, and lodged in distant parts of the body. But there is a time in the history of these cells when they are smaller and round in shape, and theoretically we would be led to believe that this is the time at which migration would occur, and not later. We know, too, that the more nearly the tumor remains in this embryonic condition as to its structure, the more malignant it is. He wished, however, to differ from the preceptor in regard to some other growths, as in cystic disease of the ovary, in which he preferred a late operation, deferring it, indeed, until the condition of the patient absolutely demanded it.

DR. BASIL NORRIS, U. S. A., in a paper on

DISLOCATIONS OF THE ASTRAGALUS,

said there is reason to believe that partial dislocation of the astragalus sometimes escapes notice. There is hardly a surgeon, he thought, who will not recall a doubtful case of badly sprained ankle, on reading over the cases of partial dislocation of the astragalus to be found among the selected cases herein reported.

An old-fashioned method of reducing a partial dislocation of the astragalus, was related to the writer by a German from the Fatherland. When a boy, he severely injured his ankle while running across a fallow field. The joint was extremely painful, as he well remembered, and was treated as a sprain. It grew worse, and was much swollen, when by good-fortune, a neighbor—and as usual, an old woman—advised him to place a brick-bat upon the foot, then to swing it

back and forth two or three times and sling the brick as far as possible. By this means the foot was jerked forward, and he was suddenly relieved.

The paper contained also the narration of a case of complete dislocation, as it happened to the speaker personally.

DR. BONTECOU, of Troy, N. Y., related a case which happened to him about thirty-five years ago, in which every possible effort on the part of force and manipulation, failed to reduce a dislocated astragalus, and he was compelled, finally, to give up the case, and allow the foot to remain in the condition in which he found it. He meets him daily, and it reminds him, as he expressed it, of his inefficiency at that time. If he encountered such a case now, he would lay all the tissues open on the outer side, restore the dislocated bone to its place, and replace the soft parts.

DR. GREGORY, of St. Louis, reported the case of a female, injured by an accident to a carriage. The astragalus was dislocated forwards and downwards. The only remarkable feature of the case, he said, was the ease with which the bone was replaced.

DR. MOORE said he was convinced that there was a little looseness in the views of surgeons in regard to this matter. It has been taught that we should exsect where there is dislocation of this bone, because it would certainly have to be done sooner or later. He thought that there were cases in which this must be done, but in many cases it is not necessary. He had seen a case a few years ago, in which the reduction was exceedingly difficult, but where it finally succeeded. He had also seen two cases in which, in addition to the dislocation, the astragalus had been split in two. In one case, one part of the bone was driven backward, so as to appear under the tendo Achillis. In the case of a woman who came under his observation, he had employed force in every direction, in his determination to restore the bone, but without success, when suddenly, under the slightest manipulation, the bone slipped into its place. But it almost instantly popped out, and continued to do so. But suppuration did not occur, and recovery was fair, with a little lameness. He met another similar case and he did nothing with it.

PROF. DAWSON, of Cincinnati, thought it would be a long time before Dr. Gregory would encounter another case in which the reduction would be "easy," as in the one he had related. He then related a case that had occurred to him in his early days of practice, where reduction could not be effected and he was not allowed to operate. The man, however, became able to walk with comparative comfort.

DR. GUNN, of Chicago, stated that it had not been his fortune to meet with a complete dislocation of the astragalus. He related a case, however, in which he resorted at once (seeing the case as a secondary one) to excision. It was a complete dislocation outward of the head of the bone. There was no necrosis. There was sufficient vascular activity in the part to prevent its occurrence. The case is of interest also with reference to the importance of primary or secondary incision. Here was a head that had retained its vitality for three months. He thought that had primary incision been made, restoration might have been accomplished. It was, however, only after a good deal of pressure had been exerted for several weeks that the shape of the foot was restored; but it became a good foot for locomotion after all.

A number of years ago, during a visit of the speaker to the country, he was shown a portion of an astragalus which had been removed from the foot so recently that evidences of blood still remained upon it. Upon examination and inquiry it proved to be the body of an astragalus which had been fractured at the neck by a fall, the individual striking on the foot, and so torn from its attachments that the surgeon simply removed it with his fingers. He then placed the bone in its proper position and the patient made a good recovery.

DR. MOORE remarked, the really interesting part of this question is how we are to treat those cases that can be reduced—whether they are to be removed at once or subsequently? Good authority, as has been said here, says to remove them at once; but good authority also says wait. I believe President Gross says immediate removal. I believe it is better to remove them early than to wait. If we remove them early, the question is whether it would not be well to extend the operation sufficiently far to enable us to see the relation of the parts and to replace them, then treating the case as one of compound fracture.

DR. NORRIS, in closing the discussion, remarked that the last case which he had reported tended to show that simple manipulation is of more importance than either force or extension. The case was a compound dislocation, which had resisted all efforts, but when, after placing the foot on a pillow, a little manipulation with the fingers was applied, an unexpected restoration of the bone occurred.

DR. P. S. CONNER, of Cincinnati, then read a paper on

EXCISIONS OF THE TARSUS.

Admirably adapted as is the foot to sustain weight, diffuse force, and secure ease and quickness of movement, it is peculiarly liable to disease and the extension of inflammation; subjected as it is to violent jars and severe twists, every opportunity is afforded for blood-extravasations in its bones and traumatic synovitis in its joints. In those subject to strumous affections, slight injuries are liable to be followed by simple inflammation or the deposit of tubercle. Specific periostitis or gumma, may produce the same effect here as elsewhere; and caries and necrosis may follow injuries to the part. Little wonder is it then that tarsal disease is of frequent occurrence, or that it at times affects a large portion of this section of the foot. What shall be done for its relief? Rest, compression, stimulant or sedative applications, always proper at first are likely to fail, and the disease goes on to the destruction of the part. Surgical treatment is then limited to—1. Opening the abscess and the removal of carious or necrosed tissue; 2. Amputation; 3. The methodical excision of the affected bones. Of these methods, amputation is generally preferred, because less likely, it is claimed, to be followed by septic infection.

There have been reported, however, a number of cases from the results of which the speaker feels called upon to reconsider the alleged dangers and disadvantages of attempts to remove only the diseased portions. He therefore tabulates one hundred and six excisions of two or more bones, several of which came under his own care. Nos. 1 and 2 of the table, are cases in which he removed the entire tarsus, all the bones being carious. The operations were followed by little constitutional disturbance, and left the patients several months after with useful limbs. The good result of these cases the speaker believed to be due to more than surgical good-fortune. Three questions must be answered in regard to the practicability of the operation: 1. Is it safe or at least attended by no greater mortality than amputation? 2. Is it likely to put an end to the disease? 3. Will the patient recover with a serviceable limb? The mortality from excision as revealed by the table compares so favorably with that of amputations in this region, that the author is led to the conclusion that, as respects the preservation of life, excision of the whole tarsus or of one of its great divisions is not much, if any, more dangerous than an ankle-joint amputation. That the disease is

very unlikely to reappear is shown by the fact, that in only two cases did such recurrence take place; but on the contrary, in a very large proportion of cases, the result was so good that the gait was fair, the support of the body firm, and locomotion easy. Motion at the ankle is generally good, and shortening of the limb but slight. No rule for operating can be laid down. Usually the lateral incision, while it renders the excision more difficult, is followed by better ultimate results than the dorsal incision. In conclusion, the speaker said: "I cannot but feel that enough has already been done by English, Continental, and American surgeons to show that the generally received opinion, that extensive tarsal disease necessitates amputation is an incorrect one; or, at least, one that requires and should have reconsideration."

THE PRESIDENT remarked that the paper just read was so comprehensive and so concise that there could scarcely be any discussion upon it. The silence of the members apparently indicated their coincidence with his opinion.

The next paper was read by DR. S. MARKS, of Milwaukee, Wisconsin, and was entitled

TREPHINING OF THE STERNUM FOR THE REMOVAL OF A FOREIGN BODY, WITH THE REPORT OF A CASE.

The paper began with the narration of a case: A soldier, Captain B., was wounded in one of the battles of the Wilderness, May 10, 1864, while in the act of rising from a recumbent posture. He was struck at a point a little above the centre of the breast-bone. The force of the ball knocked him down, but he soon arose, and walked to the rear, where he was examined by the field-surgeon, and was told that he had been struck by a spent ball, and but little injured. He, however, suffered intense pain; the action of the heart was disturbed, and the difficulty of breathing was so great as to compel him always to maintain the erect posture. He was removed to the hospital of Fredericksburg, Va., where the diagnosis was confirmed. On the fourth day, a discharge of pus gave him relief. He went to a hospital in Washington, D.C., and here many surgeons confirmed the original diagnosis, He improved so as to be able to leave the hospital,

In October, 1870, he consulted the author of the paper. Upon examination of his wound, a small spot of denuded bone was detected, and, finally, the probe passed entirely through the sternum. An improvised probe, tipped with a small portion of the stem of a clay pipe, was introduced and rotated against an obstruction supposed to be a bullet, and when removed it gave unmistakable evidence of lead.

October 15th, assisted by Drs. O. P. Wolcott, E. W. Bartlett, and Wm. Thorndike, the trephine was applied over the location of the bullet, and, after enlarging the opening with the same instrument, the bullet was extracted. The latter was wrapped in a strong cyst. The opening revealed the pulsation in the pericardium beneath. From that time on, the recovery of the patient was steady. A slight accident which caused a considerable flow of blood from the wound, during the process of its healing, rather accelerated the recovery than otherwise.

The author considers the operation of trephining the sternum for the removal of foreign bodies a new one. It is spoken of by various authors as a method of removing diseased bone, or for the evacuation of matter contained in the mediastinum, but not for the removal of foreign bodies.

DR. POST inquired whether the author of the paper considered the rapid recovery which followed the accident to be due to the loss of blood which occurred at the time.

DR. MARKS replied that he, at that time, attributed it to this occurence.

AFTERNOON SESSION.

DR. E. M. MOORE, of Rochester, N. Y., presented a paper on

SOME QUESTIONS WITH REFERENCE TO INTRA-CAPSULAR FRACTURE OF THE FEMUR.

The questions and the views which the author had formed upon them as a result of long experience may be summarized thus:

1. Is not the cause of fracture of the neck of the thigh-bone, whether intra- or extra-capsular, almost uniformly that of a blow upon the trochanter?

The writer insists upon this statement, in contradiction to the views of Sir Astley Cooper, and also that the cases of fracture either by muscular exertion alone, or by falls upon the knee, or a misstep with direct force transmitted through the bones of the limb, are too rare to be the grounds for any diagnosis.

2. Is not the preservation of the periosteum of the neck called, in connection with the reflected capsule, the cervical ligament, although only partial, the common rule, and not the exception?

This statement was confirmed by the exhibition of three specimens of recent fractures—one of three days, one of five days, and one of eight days after the injury. These were all the writer had ever seen, and were all of the same condition.

3. Does not this condition, if preserved, supply abundant nutrition to the upper fragment sufficient for entire repair?

This question is asked in reply to the opinion that the nutrition in intra-capsular fracture must depend upon the small circulation of the ligamentous tissues. If the cervical ligament remains in even a small part, there cannot be any deficiency of nutriment.

4. Is not the outer layer of what is called the periosteum of the neck, a rudimentary organ?

This opinion is defended on account of the uniform rise of the capsule from the edge of the articulations. The general law is interfered with by the length of the neck of the bone. Nature has laid down firmly on the periosteum, but retains the primary thought.

5. In reputed cases of absorption of the neck after blows upon the trochanter, said to be without fracture, is it a reasonable, much less a perfect induction, to infer a similar result, when the changes of condition are similar only in one point, and dissimilar in every other, from those cases of inflammation without a blow.

This was proved by the exhibition of cases of recent fracture.

6. Should not the induction read thus: The head of the femur and the acetabulum, not being altered, the shortening of the neck could not be from the inflammation resulting from the blow?

7. Finally, does not the practice of modern surgery produce a vastly improved result, in cases reported, as compared with the methods of the last generation?

DR. N. SENN, of Milwaukee, then read his paper on

FRACTURE OF THE NECK OF THE FEMUR, WITH SPECIAL REFERENCE TO BONY UNION AFTER INTRA-CAPSULAR FRACTURE.

This paper was founded largely upon the original investigations and experiments of its author. The experiments were made upon small animals; as a rule, chiefly upon cats. The necks of the femurs of these were broken by means of various devices, sometimes by mere force, at others by drilling, the aim always being to get within the attachment of the capsular ligament. The fractures were then treated, and allowed to remain a varying length of time, when the

animal was killed and examined. The fractures were made with a view to each of the various forms of the accident met with in the human subject. The speaker claims that, contrary to the statements of so many, we do have bony union in intra-capsular fracture; and in support of this view he not only appealed to a large number of specimens from cats, but presented also a femur from the human subject, in which he claimed to have obtained firm bony union. The remarkable feature of the case he presented was that the individual from whom it was taken had been a very old person, in whom, according to the view of many, such union is an impossibility. The specimen, the author stated, was presented at the close of last year's session by a Fellow of the Association in his absence, and as he had been informed that some doubt was expressed in the discussion as to the fact of its being true bony union, he had since that time taken the precaution. after having the specimen photographed, to boil it, This process gave no evidence whatever of any ligamentous tissue, and the author now considered the fact of its being true bony union established.

The treatment recommended was to render the adjacent joint immobile by the plaster-of-Paris dressing. The point most insisted upon was the importance of carrying the dressing well up over the pelvis, and down almost to the knee. He also considered antiseptic precautions in putting on the dressing of importance. If necessary, a light splint might be included in the dressing.

THE PRESIDENT, before calling for the discussion of the subject, expressed his gratitude to the author for the excellent paper, and his gratification at the thorough manner in which the author had pursued his investigations.

DR. BONTECOU said that he had understood Dr. Moore to state that all the cases of fracture of the neck of the femur that had come under his observation had been produced by a fall upon the trochanter. He, on the other hand, had made a post-mortem examination in two cases in which the fracture had been produced by simply twisting the limb while the foot was resting on the floor.

DR. POST called attention to the importance of not carrying our examinations too far in cases of suspected fracture of the neck, simply for the sake of making a positive diagnosis; and he related a case which had come under his observation, in one of the New York hospitals, where such anxiety for a positive diagnosis had resulted in the loosening-up of an impaction, and consequent non-union.

DR. GUNN called the attention of the Association to a case which occurred a number of years ago in the surgical section of the American Medical Association, which many would remember. A Dr. Royer requested that a committee be appointed to measure his limb to estimate the result of a fracture of the neck of the femur five or six years before. The measurement showed shortening of from two to two and a half inches. The speaker had personal knowledge of the patient at the time of injury, and remembered that the shortening was then very slight, not more than half an inch. The case, he thought, spoke very strongly for interstitial absorption.

DR. VANDERVEER narrated the experience of himself and a friend, Dr. Beach, who had procured a specimen in which they were positive that they recognized bony union of an intra-capsular fracture occurring in a young subject. They not having time to superintend the preparation of the specimen, it was boiled longer than they desired, and they found before them a characteristic specimen of ligamentous union.

DR. FIFIELD recognized in the splint presented by Dr. Senn an old friend, long forgotten. He had known it as "Marchand's spear," and had seen this gentleman use it in the Hôpital Saint Louis, Paris. He was of the opinion that fractures of the neck could be treated just as well without such extensive appliances. Position and rest are, in fact, all that is required. Mechanical appliances are passing out of date. Dr. Allis, of Philadelphia, he said, has shown us that we need nothing more than pasteboard in the treatment of fracture.

In regard to the interstitial absorption about the seat of fracture, the speaker remembered a specimen he had seen in Paris in which, two weeks after the fracture of the neck, not a vestige of the head of the bone could be seen.

DR. NANCREDE called attention to the impossibility of knowing whether a case was one of intra or extra-capsular fracture after the capsule had been removed, because, he stated, of the variability seen in the attachment of the capsule.

THE PRESIDENT, upon examining the specimen of "bony union" presented by Dr. Senn, remarked that there could not have been a fracture of that bone, or else it had been treated by a surgeon of skill that is now unknown, for the union was so close as to preclude, in his opinion, the possibility of a preëxisting fracture. He recognized in it only the evidences of senile change.

DR. SENN, in closing the discussion on his paper, defended some of the points which had been assailed, and entered more fully into the discussion of parts which had not been understood.

DR. MOORE, in closing the discussion of his paper, remarked that we must accept ligamentous union as the rule in intra-capsular fractures, but that when we refuse to admit exceptions to it, we go too far. In one of the specimens which he presented, there could be no disputing the presence of bony union; it was almost ivory.

In regard to Dr. Senn's paper, he could not see anything in the specimen presented by Dr. Senn as an impaction upon which he could found that diagnosis, inasmuch as there were no spiculæ of bone running up into the cancellous tissue, as is the rule in cases of impacted fracture. He also criticised the statement of Dr. Senn that he drew the leg down in treating it. This is liable to do injury.

DR. SENN called attention to the disadvantages under which he labored of not having read more than a sixth of his paper, and having to hurry over that, so that he had no opportunity to fortify many of his statements, and stated that in the case of fracture with bony union which he had reported, he had had ante-mortem evidences of fracture: pain, shortening, and eversion of the foot.

THE PRESIDENT remarked that shortening and eversion of the foot are two of the most fallacious symptoms we could have, and that he was forced to reiterate his conclusion that he could see nothing in the case but senile change.

In the evening a handsome

BANQUET

was given the Association by the Committee of Arrangements.

THIRD DAY, JUNE 2D.—MORNING SESSION.

TRAUMATIC ANEURISM.

The first feature of the morning meeting was the report of the committee to whom the paper and specimens of Dr. Richardson had been assigned. The report mainly confirmed the conclusions of the author of the paper.

DR. WATSON asked the attention of the Association to the method of treatment in this case. The opera-

tion had been performed and the wound dressed antiseptically. It was then not disturbed for eleven days, at the expiration of which time it was found in excellent condition. This was, he said, essentially Listerian treatment. He compared with this the result of Dr. Packard's case of reamputation, because of septic infection, and closed with the remark that the treatment must be made strictly Listerian, and we will have no suppuration at all.

DR. CAMPBELL called attention to some of the peculiarities of the case. Here had been in all probability a diffused aneurism with a very firm sac. On performing the Hunterian ligation, pulsation ceased immediately. The tumor became soft at once, and did not become gradually so. It remained as a soft tumor. Then again, what does not generally occur after ligation for the cure of aneurism, we find symptoms of gangrene. Then, instead of getting well, we find that the sac contains fluid blood; there are no layers of fibrin deposited. Above and below the sac we have the artery converted into a cord.

DR. S. W. GROSS, of Philadelphia, then reported

A CASE OF NEPHRECTOMY FOR MEDULLARY CARCINOMA, AND PARTIAL CHOLEO-CYSTECTOMY FOR CALCULUS IN THE SAME SUBJECT.

(See page 646.)

DR. J. EWING MEARS, of Philadelphia, then read a paper on

CLOSURE OF THE JAWS AND ITS TREATMENT,

with the report of a case in which complete occlusion followed a gunshot wound of the left superior maxilla, received at two and one-fourth years of age, and which was relieved eighteen years subsequently, by operation according to a new method. Closure of the jaws, he said, exists under two forms—the spasmodic or temporary, and the chronic or permanent. The former occurs usually in connection with some condition which produces irritation in the motor filaments of the third division of the fifth nerve. Among the causes we find delayed and difficult eruption of the third molar teeth of the lower jaw, tumors, abscesses, or necrosis in connection with posterior teeth, suppurative tonsillitis, and finally operations upon the lower jaw.

The treatment of these conditions consists in the removal of the causes. If necessary, remove the offending tooth or an adjoining one. After operations in this region, antispasmodic remedies should be employed, and hot water applied.

In permanent closure of the jaws, we have quite different conditions to deal with. The contraction is, in this instance, not due to perverted function, but to the formation of adventitious tissues. Although not an uncommon condition, the treatment has not until recently claimed the attention its importance deserves.

He then reviewed the opinions of all the various authors on the subject, considering also the treatment they advise, from which he summarizes the following methods of operation:

1. Excision, more or less complete, of the cicatricial bands or the osseous formation, and the subsequent employment for a long time of wedges and levers to retain the separation of the jaws.

2. Division of the cicatricial tissues and the adoption of metal shields, not only to prevent recontraction, but to reëstablish the sulcus of mucous membrane at the base of the alveolus.

3. Dieffenbach's method of simple division of the ramus of the jaw, and the formation of a false joint behind the point of contraction.

4. The formation of a false joint, originally suggested by Carnochan, with Esmarch's suggestion that it be formed in front of the contraction, and that a segment of bone be removed for this purpose by external incision.

5. The formation of a false joint *in front* of the contraction by simple division of the bone made by forceps applied within the mouth.

In closures due to anchylosis of the temporo-maxillary articulation, the methods practised are:

1. Division of the ramus of the jaw from within the mouth, either by saw, forceps, or chisel, and the formation of a false joint.

2. Exsection of the condyle with a portion of the neck, the incision being external.

The objections in cases of cicatricial contraction against the methods of operation above enumerated were stated as follows:

1. The reformation of the cicatrix and the great pain to which the patient is subjected in the use of wedges, levers, and screws; the difficulty of securing flaps of mucous membrane and skin from adjacent parts, and their successful transplantation; the almost universal failures.

2. Division and use of shields. The pain and inconvenience experienced by the patient in the use of shields, and the difficulty of obtaining the full cooperation of the patient in carrying out the necessary manipulations within the mouth.

3. The difficulty of obtaining sufficient space for free motion after the operation of Dieffenbach without division of overlying masseter muscle.

4. The loss of one-half the jaw for purposes of mastication, where excision is made in front of the contraction by Esmarch's modification of Carnochan's method. It is inapplicable where both sides are affected.

5. The difficulty of obtaining a false joint by simple division of the bone according to Rizzoli's modification of Carnochan's method.

He then related a case in which he had operated, according to this method, in the following way:

By division of the ramus of the jaw about its middle, exsection of the condyle, and division of the insertion of the temporal muscle, thus releasing the coronoid process, and effecting its removal with the condyle; division of the masseter muscle at its point of origin; non-interference with the cicatricial band. The operation was performed in this manner with the hope of securing sufficient space for free movement, and with the intention of utilizing the cicatricial band as a quasi-ligament. He believes this plan of operating novel, in that it includes the removal of both condyloid and coronoid processes with the upper half of the ramus, as well as division of the masseter, external pterygoid, and temporal muscles.

The advantages claimed for it over other methods are:

Its application to all forms of permanent closure; the utilization of the entire body of the jaw in opening the mouth, and the formation of a more perfect artificial joint.

DR. MCGUIRE, of Richmond, Va., reported the case of a child on whom he had operated for anchylosis of the pterygo-maxillary articulation. He took out a large wedge-shaped piece just at the joint with a view of making a false joint. The result was for a time gratifying; the child could open its mouth an inch and a half. Several months later, however, the child began to suffer pain in the opposite jaw, and the combined efforts of the father, the mother, and himself failed to keep those joints movable. He also reported a case in which he had cut away cicatricial bands with good results.

DR. POST remarked that he had made a special study of the subject of cicatricial contraction, and could speak with authority. He had gotten good results from

gradual but persistent dilatation of all these bands, and he claimed that this treatment must be kept up until there is no longer any tendency to contraction.

DR. BRIGGS related several cases in which he had made operations of different sorts for the relief of this condition with greater or less success. In one of them, however, after all other procedures had failed, he was compelled to excise the anterior part of the lower jaw, thus leaving an opening for the passage of blood.

DR. MEARS, in closing the discussion, said he believed the very interesting case reported by Dr. McGuire a strong argument for his operation. He was glad to hear of Dr. Briggs' operation, but he feared that operation would be of necessity followed by a great deal of deformity, and believed that it should be resorted to only after everything else had failed.

In reply to a question by Dr. Dawson, he stated that he preferred to remove both processes of the jaw, because the coronoid process, when left, interfered with the free movement of the jaw.

DR. VANDERVEER of Albany, N. Y., now read his paper on

REMOVAL OF MECKEL'S GANGLION FOR THE RELIEF OF TRIFACIAL NEURALGIA.

The author of the paper did not claim for it any especial originality, but wished to report several cases in which he had performed, with good results, the operation indicated in the title of his paper.

The first case was a man fifty-eight years old, who had suffered over ten years from severe neuralgic pain in right side of face, along the alveolar process of the upper jaw, and along the tongue. He had been operated upon several times by having the attachment of cheek to alveolar process divided. The patient will not submit to the removal of Meckel's ganglion, and the pain still continues.

Miss B., æt. 40, had suffered three or four years, from pains in right side of face. Had had all her teeth removed; had taken morphine, chloral, and the bromides, without relief. Quinine, carbonate of iron, and Brown-Séquard's neuralgic pills also failed. Finally the ganglion was removed, and complete recovery ensued.

The next was a somewhat similar case, in which the disease was caused, in all probability, by the irritation of an artificial eye, and in which the removal of Meckel's ganglion gave relief. But the relief did not prove permanent until a portion of the inferior dental nerve was exsected, and finally the diseased eye was removed.

The last patient was one in whom the neuralgia developed from a blow upon the side of the face. After being treated by a number of physicians, with many more remedies, he finally removed the ganglion, and recovery was instantaneous and complete.

DR. CAMPBELL said that he did not understand what part the removal of this ganglion played in the cure of the case. He thought rather that the removal of a portion of the inferior dental nerve was a much more important factor in the case, for a ganglion having so few sensitive filaments can surely have little to do with this disease.

DR. CONNER remarked that several years ago he had had occasion to review all the statistics of operations for the relief of this form of neuralgia. On theoretical grounds, his own belief was that the removal of Meckel's ganglion was of no real value. There is nothing in its anatomical structure or relations that would indicate the propriety of such a procedure. The operation, it is true, gives temporary relief, but it is only because it is one of great severity, and any other operation producing a similar and profound impression on the nervous system would do equally as well. You get far better results from the removal of the supra and infra-orbital nerves. In one case in which the speaker had done this there was no return of the pain up to the time of the patient's death, two years after. Any operation will give relief, but in every case a return occurs. There are cases in which no operation can possibly effect a cure, where the disease depends upon a central lesion.

DR. DAWSON reported a case in which he operated seven or eight years ago, upon a man thirty years of age, going through the antrim and dividing the nerve just as it emerged from the ganglion. There has, as yet, been no return of the pain. He reported another case, however, in which he had made a large number of operations, exsecting portions of the supra- and infra-orbital, and the inferior dental nerves, and removing cicatrices. Each operation gave temporary relief, but the pain always returned, and the patient had finally taken to his bed, transacting all his business and attending to all his duties there, as it was the only place he could be free from pain.

DR. VANDERVEER, in closing the discussion, remarked that he thought the case which he had reported where the ganglion was removed, in 1875, with no return of the pain since, was sufficient evidence of the benefit to be derived from that operation.

AN EXECUTIVE SESSION

was then held, and the Committee on Nominations reported the following

OFFICERS FOR THE ENSUING YEAR,

who were elected by acclamation:

President, E. M. MOORE, M.D., of Rochester, N. Y.
First Vice-President, W. W. DAWSON, M.D., of Cincinnati, Ohio.
Second Vice-President, C. H. MASTIN, M.D., of Mobile, Alabama.
Secretary, J. R. WEIST, M.D., of Indiana.
Treasurer, JOHN H. PACKARD, M.D., of Philada., Pa.
Recorder, J. EWING MEARS, M.D., Philada., Pa.
Member of Council, P. S. CONNER, M.D., of Cincinnati, Ohio.

(To be concluded.)

NEWS ITEMS.

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending May 26, 1883, indicate that diarrhœa has increased, and that intermittent fever and pneumonia have decreased in area of prevalence.

Including reports by regular observers and by others, diphtheria was reported present during the week ending May 26 and since at sixteen places, scarlet fever at twenty-one places, and measles at thirty-three places.

OFFICIAL LIST OF CHANGES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 28 TO JUNE 4, 1883.

ALEXANDER, CHARLES T., *Major and Surgeon.*—So much of Par. 6, S. O. 82, A. G. O., April 10, 1883, amended to direct that he be relieved from duty at the U. S. Military Academy, West Point, N. Y., October 1, 1883.—*Par. 7, S. O. 125, A. G. O., June 1, 1883.*

HEGER, A., *Major and Surgeon.*—Assigned to temporary duty in charge of the office of Medical Director Department of the South, during absence, on sick leave, of Medical Director.—*Par. 9, S. O. 55, Department of Texas, May 24, 1883.*

BROWN, PAUL R., *Captain and Assistant Surgeon.*—The extension of leave of absence on surgeon's certificate of disability granted November 23, 1882, further extended six months on account of sickness.—*Par. 6, S. O. 123, A. G. O., May 29, 1883.*

ORIGINAL ARTICLES.

ENTEROTOMY AS COMPLICATING OVARIOTOMY.

BY R. S. SUTTON, A.M., M.D.,

OF PITTSBURG, PA.

(*Read before the American Medical Association, at Cleveland, June 5, 1883.*)

IN the autumn and winter of 1881, I spent a few months in the clinic of Prof. von Billroth, at Vienna. In October, of that year, I saw him open the abdomen for a supposed fibroid tumor of the uterus or ovary. The tumor proved to be a malignant tumor of the left ovary, and was adherent to the bladder and to a loop of small intestine. Prof. von Billroth removed the tumor, cut out the infected section of bladder-wall, and closed it with carbolized silk sutures. He then removed the infected section of small intestine and united the ends with carbolized silk sutures. This case recovered and was about the ward in the fourth week. Soon after my return from Europe, this spring, the following case occurred to me:

March 25, 1883.—Mrs. H., aged 50 years; youngest child aged 17 years. After this labor had pelvic peritonitis. Has since that date complained of some distress, by her attributed to "womb disease." States that for the last nine months her life has been a burden; asks that her abdomen be opened, and, if possible, that the difficulty be relieved. Says that treatment has never benefited her, that she lives on the simplest diet, that long ago she was compelled to cease the use of cooked meats owing to pain produced in the abdomen after eating them. She stated that evacuation of the bowels was always painful, and at times almost unbearable. Her husband stated that he had spent hours injecting her lower bowel with oil for her relief. On examination: the woman was badly nourished, pale, and feeble; her abdomen was flat, the wings of the ilia standing higher than its surface; resonance on percussion was everywhere present, excepting along a line an inch above and parallel with Poupart's ligament—here the dulness was only slight; deep pressure here gave decided pain; bimanual palpation per vaginam revealed the uterus in good position, free from soreness, of proper size, with the remains of an old laceration of the cervix on the left side; to the left of the uterus, above the vaginal roof and in front of the rectum could be felt a mass which seemed to be as large as a turkey-egg; it was movable in an upward direction, and I grasped it entirely with the fingers of the two hands; it was tender, and she complained of the pressure; bimanual palpation per rectum confirmed the statement already made, and the pain on pressure now made was earnestly complained of.

It was my conclusion that the body felt consisted of the left ovary, and probably the fimbriated extremity of the Fallopian tube in a state of chronic inflammation, or more properly of hypertrophy, congestion, adhesion, and hyperæsthesia. There was no room for me to suggest laparotomy in the case. The woman gave me to distinctly understand that unless I would open her abdomen that my services were not to be employed. I assented to her request, and on March 28th with my two assistants, Drs. Rahauser and McDonald, and in the presence of Dr. Emmerling, also assisting, I opened her abdomen. I readily found the mass in the pelvis, it would not come up into the abdominal wound until detached with the finger from the sigmoid flexure of the colon. When brought well into view, it was found to consist—

1st, of the ovary not much enlarged.
2d, of the fimbriated extremity of the tube.
3d, of the broad ligament.
4th, of a loop of the small intestine, so fixed that it was curve-shaped in the mass, then passed along, firmly adherent to the broad ligament, up to the fundus of the uterus itself.

The entire mass was a conglomerate of ovary, tube, ligament, and gut.

The gut-wall was thick, and evidently a large mass of organized lymph had glued long ago all together.

My first impulse was to close her belly, but I remembered the patient's request as I lifted her feeble body on to the operating table. It was, "Now, Mr. Sutton, you take that out or let me die." With the finger I detached the gut from the mass and from the broad ligament nearly to the fundus of the uterus, and laid the gut on the surface of the belly at the margin of the wound, and turned around to wash my bloody hand and for a moment's reflection. When I turned again from the wash-basin, my second assistant was holding one end of the gut between his thumb and finger outside of the belly, the other end of the gut was in the cavity of the belly. It had broken off by its own weight, and the slightest traction to arrest its recession into the belly. I recovered the lost end, dissected it entirely free from the broad ligaments all the way up to the uterus, and securing each end with forceps, above the diseased tissue, I cut away all the diseased portion of the cut—about four inches. I now removed the ovary and adhering tissues, securing the base by ligature cut short. All diseased tissue being now removed, I united the ends of the gut with silk sutures and a curved needle, after the manner of Czerny, as taught me by Prof. von Billroth and his assistants, Mickulicz and Wölfler. Twenty or twenty-two sutures were put in. The belly was well cleaned out, and a long glass drainage-tube was placed in the wound, the lower end of it reaching the bottom of the pelvis.

The abdominal wound was closed, dressed, and the patient was put to bed. One hour was consumed in the operation. No spray was used. The silk (non-carbolized) was simply well scalded, as were also all the instruments. Before beginning the operation, the hands of all were well washed, and then rewashed in five per cent. carbolic-acid water. The drainage-tube remained forty-seven hours, and through it bloody serum was drawn in small quantities for thirty hours; clear serum then appeared, and the tube was removed seventeen hours later. No drug excepting opium was given. The highest temperature reached was 101° F. on the first night. It fell on the following day to 99.5°, and but once afterwards reached 100°—viz., on the twentieth day, when her ignorant husband gave her a dinner of veal. On the third day, she was passing gas per rectum. At the end of the fifth day, the pulse was 88, temperature 99.4° F.

On the 11th day, pulse 90, temperature 98½°; the stitches were all removed on the previous day. No tenderness on gentle pressure existed over the abdomen, and the rectum was filling up with fecal matter.

On the 12th day, the rectum was emptied by an enema and the finger, and an hour or less later the lower end of the colon was also emptied with a little additional water. The bowels moved spontaneously on the 20th day. Up to that time enemata were resorted to frequently. Up to the 16th day the diet was soups and barley, and toast and water. Solid food, beginning with bread, was given; afterwards raw steak. On the 19th day, pulse was 72, temperature 97⅘° F.

On the 21st day she rose and got out of bed to the commode, and the bowels moved spontaneously.

On the 22d day, she was again out of bed for a movement of the bowels.

From the 22d day to the 25th day after the operation she received no medical care.

On the 25th day her family physician took charge of her, and at this writing 70 days have elapsed since the operation. She is going about, and taking solid food.

These cases prove the possibility of avoiding the making of artificial anus in wounds of the small intestine, and the resection of portions of the gut in some cases of hernia where the gut has become gangrenous.

Resections of portions of the intestine have frequently been made abroad, notably by Billroth, Czerny, and Von Wahl. The specimen is here for inspection, also a remnant of the silk used, and also the Kœberlé forceps used to secure the ends of the gut, as well as the curved needle with which the sutures were introduced. The specimen shows full four inches of the gut, and the left ovary but little enlarged. The gut was adherent to the ovary over nearly its entire circumference, and a well-marked stricture of the gut is seen. The wall of the gut is thick from inflammatory deposit, and has undergone at the point of stricture marked fatty degeneration.

The thickening of the muscular tunic beyond the adherent portion is also well marked, and this thickening of the muscularis was a great aid in the introduction of the sutures.

HAVE WE ANY THERAPEUTIC MEANS, AS PROVEN BY EXPERIMENT, WHICH DIRECTLY AFFECT THE LOCAL PROCESSES OF INFLAMMATION?

BY C. B. NANCREDE, M.D.,

SURGEON TO THE EPISCOPAL HOSPITAL, PHILADELPHIA.

(*Read before the American Surgical Association, Cincinnati, May 31, 1883.*)

BELIEVING that the true aim of a paper read before this Association should be merely the indication of the salient points of the subject, in order to elicit as full discussion as possible, I shall omit all such details as are non-essential. It will be impossible for me, in the time assigned, to answer the query forming the title of my paper except with regard to the early stages of inflammation. Owing to press of work, I have also been unable to pursue my investigations as far as I had wished, and should therefore prefer to entitle my paper "A preliminary note as to whether we possess any therapeutic means, as proven by experiment, which directly influence the local processes of inflammation." I trust that any apparent neglect to specifically mention the sources of my knowledge will be set down to the necessary brevity of this paper, and to the fact that all of you must be more or less familiar with the sources whence my facts are culled.

Careful study of the essential processes of various morbid conditions, has often led to the theoretical employment of therapeutic measures, which by their apparent practical use have confidently encouraged their future employment. Clinical proofs, however, always embody the inherent weaknesses of careless or prejudiced observation, with the varying unknown quantity of the effects of the *vis medicatrix naturæ*.

But if in addition we find by experiment that our *a priori* therapeutics when experimentally applied in the case of animals, actually produce the precise effects which we have pre-determined will probably prove efficacious, then we can hardly go astray in confidently applying similar treatment to the human subject. If now we find clinical descrepancies, it must be our aim to ascertain the exact limitation of the remedy for good or evil, and the precise indications for its employment, instead of thrusting it contemptuously aside, when we fail of the expected result, the failure being probably our faulty method of applying the treatment and not self-inherent. Upon the other hand we must always hold before our eyes the experimental mirror of what has been and can be effected, and not expect to do what we have demonstrated is an impossibility.

This paper is avowedly written in advocacy of bloodletting in general, but chiefly of the local abstraction of blood. This once much-vexed question seems again pressing for solution, as the pendulum of unreasoning prejudice and authority, having reached its furthest limit on the side of proscription, is now slowly swinging back to an opposite point, the stability of which must depend upon the possibility of satisfactorily answering the ques-

tion contained in my title. If the answer be favorable, the revival of bloodletting will be founded upon the only sure basis, viz., that of demonstrated scientific facts which will replace the purely theoretical dicta of authority, which, like the will-o'-the-wisp, led our forefathers into such an erratic use of the lancet that it wrought not only by its abuse its cure, but an almost total abolition of bloodletting, which I for one regret.

A rapid review of the minute processes of the earlier stages of inflammation, coupled with a consideration of some facts relating to the physiology of nutrition, will form a necessary preface to the body of my paper. I shall refer only to the early stages of inflammation, for, of course, no direct effect can be exerted upon the tissue changes of that process, when the inflamed part has returned to its fœtal state—is merely embryonal tissue, only a step further from which is pus.

Examining with a low power, we find that the arteries are normally about one-sixth smaller than the veins, and that "in every artery a space can be distinguished within the outline of the vessel, which is entirely free from corpuscles." The arterial current is the more rapid, and it is appreciably accelerated at each beat of the heart. As to whether there is or is not a primary contraction of the arteries in the first stages of inflammation seems to depend so much upon the irritant used that I shall pass the question by as unimportant for our present purposes. The first change noted is an enlargement of the arteries, which become tortuous, the veins following suit; but there is "a time when, instead of the arteries being sensibly smaller" than the veins, "they far exceed them in diameter." Note this fact carefully. Contrary to expectation, at the outset the circulation is accelerated in the dilated vessels, but the rate soon becomes normal, and is succeeded by a slowing, then an oscillatory movement, a temporary stagnation; again a resumption of the flow, and finally permanent stasis, with crowding of the vessels—the veins especially—with cell-elements, so that the previous clear space existing along the walls of the arteries can no longer be detected.

The obstructions seem to consist solely of red cells, which are so closely packed as to render "their individual forms" . . . "scarcely distinguishable." Free diapedesis of the white-blood corpuscles now takes place, with exudation of liquor sanguinis, both processes having commenced when incipient stagnation set in. The experiments of Ryneck and H. Weber have demonstrated "that in an injured part, the walls of the capillaries become so altered that the liquor sanguinis, instead of transuding from the smaller arteries in quantities just sufficient to balance the absorption, leaks abundantly from the vessels, and that in many cases this is subsequently associated with squeezing out of the leucocytes, or even of the colored corpuscles." The consequence of this free exudation is that, owing to increased pabulum—liquor sanguinis—the cells of the inflamed area multiply until, in many instances, we have the tissue reverting to the fœtal state, when it consists merely of embryonal tissue—viz., a mass of indifferent cells held together by a small quantity of intercellular cement, which latter has only to liquefy, and *pus* at once results.

The remaining subsidiary phenomena of inflammation being non-essential, are purposely omitted.

To summarize the whole process in the words of Dr. Burdon-Sanderson, "the circulation is at first accelerated and increased, subsequently retarded and diminished," and "the latter condition is attended with exudation of liquor sanguinis, migration of leucocytes, and stasis."

That the primary acceleration of the blood-stream is in some way dependent on reflex nerve action seems clear. At this point, our researches into the essential phenomena of inflammation may cease. A few physiological facts demand consideration before I sum up what *a priori* reasoning indicates as to the therapeutics of the early stages of inflammation. Ranvier has shown that the white-blood cell is sluggish, and then ceases to move in the absence of oxygen, and is active in proportion to the amount of that substance present. It is also indisputable that the red cells are the main carriers of oxygen, and that if their numbers are relatively increased to the fluid in a given bulk of blood, especially if, as in inflammation, both the necessity and capability of the cells of the tissue making use of the oxygen are removed, at once an excess of oxygen obtains, *i. e.*, an increased amœboid action of the white cells not only is possible, but becomes a necessity. Physiology teaches us that only so much of the constituents of the blood-plasma exude or are withdrawn by cell-action as suffice for the normal function of the parts, and that, if any excess is present, that the lymph-spaces return it into the lymphatics, whence it passes into the general circulation. If, however, the lymph-spaces are compressed by dilated bloodvessels, and crowded with migrated cell-elements, the excess of pabulum must be retained, with a consequent stimulus to undue cell-proliferation. Precisely this obtains in inflammation. But physiology likewise shows us that there is a certain attraction exerted upon the blood-current by the tissue-cells according to their varying wants which not only aids the *vis-a-tergo* action of the heart, but actually determines to a certain extent the amount of blood present at any given time, for instance, in a gland. If this action obtains in health, there is no reason to doubt it is still more potent in disease. From the physiological fact upon the one side that only so much pabulum is withdrawn as suffices for healthy function, and, on the other, that in inflammation this material is in great excess, it seems proven, viewed from the light thrown upon the subject by the experiments of Ryneck and Weber, that, in some way, the capillary walls are injured by intra-vascular pressure.

To summarize: (1) Intra-vascular pressure injures the vessel-walls, aided, perhaps, by the constant passage of the white cells; in consequence, an inordinate amount of blood-plasma exudes, which stimulates cell-proliferation. (2) The accumulation and stagnation of the red-blood cells, with the draining-off of the liquor sanguinis, cause a relative excess of oxygen, which excites to increased

amœboid action the white-blood cells and their consequent migration. By the study of the phenomena of osmosis, we learn that stagnation of fluid and intra-vascular tension induce outflow; but reverse the latter condition, increase the rapidity of the circulation, and, with the constitution of the blood, an outflow must result.

From these studies I am forced to conclude that a theoretically perfect remedy for incipient inflammation must comprehend the following effects. It must either lessen the *vis-a-tergo* of the heart's action—so as to prevent injury to the vascular walls by over-distention and the consequent outpouring of liquor sanguinis; it must prevent such an ingress of blood into the affected area as would produce the excess of oxygen, the migration of cells, the blocking up of the lymph-spaces, etc.; or what would practically amount to the same thing, it must so lessen the difficulty of escape on the venous side, that howsoever great the *vis-a-tergo*, a ready draining off, nay, aspiration, as it were, of the venous blood may occur; if possible, both these effects must be produced. The last requisite would be that the remedy must increase the frequency while it lessens the force with which the heart acts, for although, whatever, would lessen the *vis-a-tergo* would prevent any further outpouring of pabulum, yet that which was already exuded must remain, and would have to be consumed before the initiated cell-change could cease. In my experiments on the frog's tongue I noted all the vascular changes described in the earlier part of this paper. When the stasis was complete, a large vein on the distal side was divided, *i. e.*, local bleeding was effected from the vessels directly leading from the inflamed area. I purposely avoided opening the vein on the cardiac side of the phlogosed spot lest I might simultaneously divide the supplying artery. By severing one of the ranine veins at a point where I could distinctly see that the venous radicles of the inflamed area emptied, I achieved my purpose without further damage.

The effect upon the obstructed vessels was first an oscillation of the blood disks, then an occasional momentary flow of blood, then suddenly a rapid resumption of the circulation sweeping out the bloodvessels, and apparently restoring them to their normal condition, except at spots where the agents inducing the inflammation had chemically destroyed the vessels or coagulated their contents. I do not presume to say that the white corpuscles betook themselves at once back again into the bloodvessels, for I did not use sufficient amplifying power to observe this, nor was I then dealing with any other processes than the vascular changes. I should have carried my researches much further had I not seen that nothing was needed beyond a mere corroboration of Gensmer's admirable paper, which I shall now quote:

"At the present time it is generally accepted, that by local bleeding inflammatory stasis is relieved, but this view has not been demonstrated; many adhere to the derivative action of bleeding and many still believe in the loss of blood as such, in the amount of blood drawn. The web of the foot of a curarized frog, was burnt with a red-hot pointed needle, or with nitrate of silver." . . . "As soon as" . . . "slowing of the current and stasis had taken place, a leech was placed near the hock-joint." . . . "As soon as sucking began, the picture under the microscope changed in a striking manner. The blood-current was immediately accelerated, blood corpuscles which adhered to the wall passed into the blood-current, stasis was relieved, briefly, the inflamed capillary loops were in a short time, sometimes in a few minutes, entirely free, and presented in a few cases at the termination of the experiment, the appearance of a perfectly normal and even accelerated circulation." The authors were unable positively to determine whether the migrated white-blood cells "were in any way influenced by the bleeding." Owing to the tardy rate with which the blood was effused after scarification, the author stated that the good effects were not comparable to those of leeching. In like manner general bloodletting by opening an abdominal vein was inferior to leeching near the affected area. Dr. Gensmer considers it proven "that the antiphlogistic effect of local bleeding is due to a purely mechanical cause. Through the stronger current caused by the sucking of the leech (or by a cupping-glass, or by scarification) is the blood corpuscle which adheres to the wall in the inflamed territory torn away, the obstructed capillary perfectly opened and there is a normal, indeed a temporarily stronger circulation established." . . . "Local bleeding prevents stasis. Bleeding not only does not cause local anæmia, but even occasions (of course transiently) arterial hyperæmia, that is, it causes a more intense flow of arterial blood to the inflamed point. Further, this abundant supply of arterial blood results in a better nourishing of the tissue, and that, therefore, the tissue is better able to withstand the effects of the inflammatory process is to be expected. It further follows that the antiphlogistic effect of bleeding depends upon the quantity of blood drawn, and that in the first place only the rapidity of the current is to be considered. Evidently the bleeding must take place when possible between the inflamed point and the heart, and not far from the former."[1]

What the effects of bloodletting are upon the general circulation has an important bearing upon the subject we are now discussing. According to the latest authority, "The water is increased, and the globules," . . . oxygen carriers, "*are diminished* in relative amount." . . . "The action of the heart becomes *more rapid* and its force lessens"—the italics are mine—"the arterial tension falls." But how about the evil effects of bloodletting? "It is a remarkable fact perfectly well known to old practitioners, and to which Sir James Paget has recently called attention, that the ill-effects of bleeding in healthy subjects are very temporary and easily repaired. The blood globules, which are relatively more affected by bleeding than

[1] Dr. Alfred Gensmer Halle. Centralblatt für die medizinschen Wissenschaften, April 1, 1882.

the other constituents, are quickly reproduced." . . . As surgeons, we must all have had ample proof of this fact. Some years since while pursuing other investigations upon human blood, I observed the same fact and noted it in the published report of my work. I need hardly point out, that if my experiments with those of Gensmer's are reliable, and the other facts quoted are really facts, our ideal remedy is found. From the quotations given of Gensmer's paper, it is clear that our experimental results exactly tally. I think, however, that the superior advantages of leeching over scarification, etc., can hardly be similarly obtained in the human subject since the relative size of the leech to the frog must have had a considerable share in effecting the good obtained by an actual aspiration of the blood. In my own experiments, by dividing a large vein in the tongue, I obtained the effect of bloodletting pure and simple. To produce the best results, then, we should, when possible bleed from one of the principal veins leading from the inflamed focus. When this is impossible, leeching or wet-cups should be resorted to, since by both the mechanical effects of aspiration are superadded to the mere outflow of blood. But many authorities maintain that bloodletting can be dispensed with in all cases, for exactly the same results are obtained by the use of arterial sedatives. To test the truth of such statements it is only requisite to experimentally induce inflammation, and then give a large dose of gelsemium. The arteries are seen to become smaller, the current slower, and if stagnation has already occurred, it increases or remains stationary. This and similar remedies then reverse that which both upon theoretical and experimental grounds we have found to be most effectual. They certainly also interfere with the rapid absorption of effusions.

From a review of the facts set forth in this paper, I think I am warranted in stating the following propositions as the logical and practical outcome of my investigations:

(1) During the stage of dilated arteries, with increased rapidity of the current, but little danger of capillary changes with exudation need be apprehended, and here perhaps ergot, certainly arterial sedatives do good, either directly or indirectly, without bloodletting, by reducing the size and rapidity of the current, thus allowing the veins of the irritated area time to empty themselves, even of an unaccustomed amount of blood. Thus if vascular-pressure changes have taken place, the vessels have an opportunity to return to the norm.

(2) After stasis has occurred, or while it is occurring, weakening of the heart's action and a diminished volume of the current—*e. g.*, the effect of arterial sedatives—can do nothing but harm to the inflamed area, although, for the reasons given in proposition 1, it may prevent extension of inflammation in the circumjacent parts, which are merely in the earlier stages of congestion.

(3) The results to be sought, and which are secured by local bloodletting, are removal of the blood on the venous side, so that the vessels can not only empty themselves, but a certain amount of *vis-a-fronte—i. e.*, aspiration—is invoked: this secondarily results not only in a temporary return to the norm on the arterial side, but an increased rapidity (and here is an important point)—lessened force of the circulation. The acceleration of rate without the weakened force of the circulation would further damage the vessels, instead of which the increased rate of the current merely serves to sweep out the accumulated red-blood cells, the cause of the excess of oxygen, and the consequent cell-migration. The vehement current also induces a rapid resorption of the effused liquor sanguinis, at once the stimulator to growth, and the food of the cells. This latter advantage is not founded on theory alone, for it is a matter of common observation that the mere amount of blood extracted produces no sensible effects on an inflamed breast, for instance, *at first*, but in a few hours, the skin, if carefully examined, has become wrinkled, and the organ shrunken. This effect is secondary to the loss of blood, and chiefly results from the absorption of the inflammatory exudate.

(4) Arterial sedatives in the later stages are usually inadmissible except as succedanea to bloodletting, as far as the focus of inflammation is concerned: the surrounding parts, which are merely congested, may be benefited by their exhibition. After bloodletting, they act favorably, because, when the stasis has been overcome, they lessen intra-vascular pressure, and thus permit the blood-vessels to recover their normal condition. They also alleviate pain by lessening the bulk of blood in the part—*i. e.*, they relieve nerve-pressure.

As before intimated, this essay is in reality little more than a few notes on the effects of local bloodletting, and does not pretend to cover the extended field of either the local or general treatment of inflammation. If my remarks prove fruitful in the way of an instructive discussion, which may induce some of my hearers to resort anew to this useful but neglected remedy, I shall feel amply rewarded.

MEDICAL PROGRESS.

Injections of Arsenic in General Sarcomatosis.—Prof. Köbner reports a case which still further confirms the value of Fowler's solution of arsenic in cutaneous diseases. Two years ago, the patient, who was eight and a half years old, and has always been delicate, developed sarcomatosis of the skin, which gradually spread, until almost the whole cutaneous surface was affected. Köbner commenced injecting Fowler's solution in distilled water, in proportions of one to two; from two and a half to four drops of the arsenical solution being used at each injection, thrown under the skin or into the muscular tissue of the gluteal region, and into the stroma of some of the larger tumors. In three months five injections were made, ʒij of Fowler's solution being used. At the end of three months the tumors were considerably diminished, having disappeared in some places, leaving a brownish cicatrix. Equal parts of the arsenic solution and distilled water were then used, six to nine drops being injected; in about forty days ʒiv of Fowler's solution being used, with progressive amelioration of the symptoms, the lymphatic glands being greatly reduced in size, and the liver and spleen reduced to the

normal diameter. The quantity injected was then gradually reduced, and in one year from the commencement of treatment, nothing was left of the disease except a few cicatrices showing the former position of some of the larger tumors.—*Gaz. degli Ospitali*, May 13, 1883.

SUCCUS CONII IN CHOREA.—DRS. CLIFFORD ALLBUTT, EDDISON, and CHURTON have obtained good results in the treatment of chorea, with violent movements, by large doses of succus conii. The patients took from ℥ij every hour to ℥ss every four hours during two or three days. It was given sometimes alone, sometimes in combination with morphia or bromide of potassium. It seems that the best results would be obtained by large doses at first, until the system is thoroughly under its influence, when smaller doses, frequently repeated, will keep up its action. No toxic effects were ever noticed in these cases. The cases seem to show: 1. That the drug, to be of any service, must be given in large doses. 2. That its action must be sustained by frequent repetitions of the dose at short intervals. The uncertainty of the action of given specimens of succus conii necessitates great care in its administration, and militates against its general adoption. But cases in which neither chloral nor morphia have any effect may arise, and in which, as in the above, succus conii may prove efficacious.—*Lancet*, May 26, 1883.

GELATINE TEST FOR ORGANISMS IN WATER.—DR. ANGUS SMITH, of Manchester, has recently brought forward this new test for the detection of organisms in water. It consists in rendering the water thick by dissolving gelatine in it. If pure, the gelatine cylinder remained long unaltered; but if the water be impure from the presence of organisms, the gelatine round the organisms becomes liquefied and globular, the organisms remaining solid at the bottom of the spheres.

Dr. Angus has prepared photographs of test-tubes of water which had been thickened by a solution of the purest fish-gelatine, and then exposed to the action of light. When the water was pure it remained translucent; but when bad, bubbles were rapidly formed, and the bacteria which appeared to be in the water began to act on the gelatine, breaking it up and rendering it soluble. A rapid movement of gas was observable. When the bubbles or balls appeared to be spherical they were aggregations of bacteria. This change took place quickly—almost in twenty-four hours. But a peculiarity of the test was this: that it was only applicable where infusorial animals were present. For instance, peaty water in which there were no animalcules or bacteria would stand without breaking up the gelatine. In order to change the gelatine bacteria must be present. Organic matter that is not putrescent or infective will not do it.—*Med. Times and Gaz.*, May 26, 1883.

TURPENTINE VAPOR-BATHS IN GOUT AND LITHIASIS.—M. BRÉMONT, FILS, has recently submitted a memoir on this subject. The turpentine employed is that of the cedar, and its vapor is absorbed by the skin from a vapor bath. That the remedy is absorbed is proved by the fact that the urine acquires the characteristic odor of the turpentine. During the first five or six days of the treatment there was a marked increase of sand in the urine of patients with uric diathesis, but this phenomenon does not indicate an exacerbation of the affection, for the quantity of sand rapidly diminishes after this and finally disappears entirely. These happy results persist for a long time after the vapor-baths are discontinued.—*Gaz. Hebdom.*, May 4, 1883.

BACILLUS OF TYPHOID FEVER.—PROF. EBERTH, of Halle, has recenly written a paper on the bacillus of typhoid fever, in connection with one from Volkmann on the bacillus of typhus. It is well known that Klebs has already published the results of his researches on this subject. According to Eberth, these bacilli differ from others by their rounded extremities, and by their feeble power of absorbing staining matters. They are smaller than tubercle-bacilli; they are present *en masse* to a less degree in ganglia, and contain small cellular-like bodies, which are, perhaps, spores. These are not the only organisms found in typhoid, seven other species being differentiated. Nuclear infiltration of the intestines, ganglia, and spleen contained a great number of them. In one case, when the disease was at its apogee, their number was greatly diminished, which may explain the negative results in a number of cases. Eberth found the bacilli eighteen times in forty cases. He is supported by the results of Klebs, Koch, Meyer, and others. In twenty-four various affections, of which twelve were cases of intestinal tuberculosis, the bacilli of typhoid were not once found: Meyer, in six cases of scarlatina, measles, and diphtheria, was equally unsuccessful in searching for them. Eberth believes that the bacilli are most constant in the intestinal mucous membrane and in the mesenteric glands, whence the blood-current carries them to the spleen. So far, attempts at cultivation and inoculation have not been successful. [The experiments of Maragliano, of Genoa, have already been published.]—*Progrès Méd.*, May 19, 1883.

CHLOROFORMIZATION DURING SLEEP.—In the *Medical Record* for April 28, 1883, DR. JOHN H. GIRDNER takes the ground that chloroform narcosis cannot be produced during sleep, and supports his position by giving the details of five trials, all failures. The chloroform was poured on a folded towel and held about eight inches from the sleeper's face. One of the persons experimented upon awoke at the end of two minutes, the others in three. DR. DAVIS HALDERMAN, in a letter to the *Medical Record*, June 2, 1883, on this subject, quotes cases which show conclusively that chloroformization can be produced during sleep, and that the chloroform should be administered from a handkerchief held, at first, about twelve inches from the sleeper's face, and gradually brought nearer; though in two cases reported in the *Pac. Med. and Surg. Journ.*, Jan. 1874, the anæsthetic was poured on a piece of surgeon's lint and held as near to the face as possible without actual contact; both cases were successful. Dolbeau made twenty-nine experiments, with a view to determining this question, on persons of both sexes and of various ages; ten were completely successful. Dr. Girdner's experiments were all made in the same manner, although all were failures, and it is justly remarked that under these circumstances different methods should have been tried.

BACILLI OF TUBERCLE.—M. COCHEZ, who has made numerous investigations on the presence of the bacilli tuberculosis in sputa, has come to the following conclusions: 1. An examination of the sputa of tuberculous patients shows the constant presence of the bacilli. 2. The larger or smaller number of these elements may furnish data regarding the progress of the disease. 3. The absence of the bacilli, established at several different times, is strong ground for rejecting the diagnosis of tuberculosis. 4. The sputa of phthisical patients constitutes a favorable medium for the culture of tubercle-bacilli; hence it is necessary to take careful antiseptic precautions to prevent their propagation.—*Gaz. Hebdom.*, May 25, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, JUNE 16, 1883.

COMPLICATIONS OF EXOPHTHALMIC GOITRE.

THE classical symptoms of exophthalmic goitre are sometimes diversified by other nervous disturbances. The rapid and irregular action of the heart, the enlarged thyroid, the dilated cervical vessels, and the protrusion of the eyes, constitute the quaternary of symptoms which give to this disease its special characteristics. Besides these necessary symptoms, there are accidental complications, which impart variety to its monotonous symptomatology. These complications may be in the mental or moral sphere, or may involve the motor and nutritive functions.

Trousseau was the first to recognize the changes in the character and disposition which in some cases distinguish this disease. We have encountered a case in which the appearance of the malady seemed to be due to a profound moral emotion. A lady, just before retiring, received some distressing intelligence; in the morning, to her extreme amazement, her appearance was so changed as to be scarcely recognizable, in consequence of a considerable exophthalmos and enlargement of the thyroid. In another case, during the course of the disease, various kinds of morbid fear, melancholia, and wakefulness, were pronounced symptoms. In all the cases which we have observed, there were various changes of the disposition, as distrust of others, fretfulness, morbid self-consciousness, etc.

The moral perversions are less important than the epileptiform, but the latter are much less common. Dr. Ballet, in a communication which we find in the *Revue de Médecine*, of April 10, 1883, has been able to collect five cases, in addition to the observation of Gildemeester, which is usually referred to by the writers on this topic. In the first case, the epileptic seizures which had occurred for many years disappeared when the exophthalmic goitre came on. Dr. Ballet's cases are divisible into two classes: those in which the convulsive seizures and the exophthalmic goitre succeed and supplant each other; those in which the two maladies continue separately in the same individual.

Of the five cases whose histories are given in detail, there is one corresponding to Gildemeester's, in which attacks of epilepsy ceased when exophthalmic goitre appeared; and one in which these phenomena were reversed. In the second group of cases, the convulsive seizures appear to have the relation of epiphenomena, and grow out of the circulatory disturbances belonging to Graves' disease. The epileptic attacks are not habitually present; the disease is exophthalmic goitre, and this has, as an accidental complication, the convulsions.

Many cases of Graves' or Basedow's disease have been complicated with paralysis, with hemiplegia, and with paraplegia; others with hysterical paraplegia, hemianæsthesia, and similar hysterical affections. They may therefore be durable or permanent, or temporary; in the former dependent on structural changes; in the latter due to mere functional disturbances. From these facts it may be concluded that there are probably two types of this affection. Clinically, this appears highly probable. There are cases of exophthalmic goitre which occur suddenly, which behave in their course as other neuroses, and are not accompanied by any organic changes; there are others which develop slowly, and manifest by the permanence of the lesions, actual and complicating, the permanent character of the affection. As respects the latter, it is an interesting fact that Filehne has produced the trinity of symptoms of which this malady is composed by experimental lesions of the restiform body.

Another group of complications are those which involve the nutritive functions more especially under the control of certain nerve-centres. These are polyuria, diabetes, and albuminuria. These affections are by no means unfrequent complications of exophthalmic goitre. They are, properly speaking, epiphenomena, and they serve to ally this disease on the one hand with the organic affections of the nervous system; and this relation may help to explain the affiliations of polyuria, diabetes, and albuminuria with each other. Of these complications, diabetes is held to be the most common. In a case which has occurred under our observation, in a young man, exophthalmic goitre, in a perfectly typical form, succeeded to an attack of albuminuria, so that when the former was fully developed, the

latter had disappeared. On the disappearance of the albuminuria, a notable quantity of sugar was found in the urine, which was then passed in considerable amount.

In a recent discussion on diabetes, which has occupied the Pathological Society of London for several weeks, the origin of the disease in structural changes in the brain, notably along the floor of the fourth ventricle, met with little favor, and indeed appeared not to be sustained by the pathological evidence. The facts there given supported strongly that view of diabetes which refers it, as Pavy does, to chemical changes in the blood. The remarkable way in which exophthalmic goitre is related to certain complications, and the transmutations which occur between them, seem to indicate a community of origin, and a common source of pathological affinity, seated in the pons and medulla.

SEWAGE POLLUTION OF WATER SUPPLIES.

IN the annual report, for 1882, of the Chief Engineer of the Water Department to the City Council of Wilmington, Del., we find a carefully prepared paper by Prof. Leeds, of the Stevens Institute, giving the results of an investigation into the water-supply of the city. Prof. Leeds describes the methods of analysis by which his results were obtained, and for the benefit of those who are not familiar with sanitary chemical work, he explains what is meant by a "standard of purity," and interprets his results by a comparison with such a standard.

There is no doubt that the chemist can determine with the utmost exactitude, exceedingly minute quantities of the elements of organic matter existing in water, and if these quantities do not exceed those which have been found in water of similar origin and history, which daily experience shows to be wholesome, he may consider himself warranted in classifying the water yielding such results as pure, but its wholesomeness can only be assumed, for the poison of fever or other specific disease may exist in it, undetected by the chemical tests. It is very probable that a water containing such minute quantities of organic matter is wholesome, but its wholesomeness does not follow from the laboratory results. On the other hand, if the quantities found exceed those which may be considered normal to waters of similar origin, he may be warranted in classifying the specimen under investigation as impure, but it by no means follows that it is therefore unwholesome. It is true that there is a greater probability of the presence of a specific disease-poison where there is much organic matter present than where there is not much, but it is only by assumption that the unwholesomeness can be predicated.

It was not, however, to point out the distinction between impurity and unwholesomeness, so apt to be forgotten by the chemist, that we referred to Prof. Leed's report, but to indicate what seems to us, as medical men, a danger to which false economy and the restricted scope of the chemist's laboratory tend to expose us. It is well known that running water becomes purified in its progress. "I hold, therefore," says Prof. Leeds, "that the statement so frequently made, that water once polluted by sewage cannot again become safe for drinking purposes after flowing any number of miles, is contrary to our common experience and observation." He instances the Passaic, which although contaminated by the sewage of Paterson, N. J., a town of fifty thousand inhabitants, returns to, or nearly to, its normal standard of chemical purity at a point sixteen miles below, where it is pumped up for the supply of the three hundred thousand inhabitants of Jersey City and Newark. Organic matter, generically speaking, becomes oxidized during the flow, and disappears transformed into harmless ammonia, which is evanescent, or into equally harmless nitric salts; but there are grounds for belief that the poisons of specific disease are less susceptible to oxidizing influences, and their particles may be present in full virulence although widely separated by the large mass of the flowing stream. Filtration through the soil is infinitely more efficient as an oxidizing process than surface flow, yet there are many lamentable examples of percolation of typhoid sewage into wells where the oxidation has failed to destroy the noxious organic matter.

From the medical point of view, the water of a stream which has been contaminated by sewage ought not to be used as a general supply on the dictum of the chemist until he can show that the specific poison is destroyed by its course of sixteen miles, as surely as the mass of organic matter which accompanies it, or until the medical statistician can inform us that typhoid fever and other diseases known to be propagated by means of water, do not prevail in cities which trust to purification by surface flow.

THE HEALTH OF THE GRADUATES OF WOMEN'S COLLEGES.

IN our issue for October 14, 1882, we commented on the differing opinions as to the health, good or bad, of women who had gone through a college course, and said: "If the future mothers of our country are being ruined physically by our methods of education, who would wish, with such downright earnestness of purpose, to remedy the impending evil as our educated women themselves? If a false cry is being raised which will hamper the just and wholesome intellectual development of

women, who are more interested in showing it than the graduates of our women's colleges?" We commended the matter to the "Association of Collegiate Alumnæ," and urged a fearless and a thorough examination of the facts.

We are glad to see that our suggestion has been acted upon. The Committee of the Association on Health Statistics, consisting of representatives from twelve colleges for women, has just issued a blank form for a "health return" from each "alumna," on the back of which the two sentences we have above repeated are quoted. The document is rather formidable in length, covering fifty questions under these seven headings: Conditions of Childhood, Individual Health, Family Health, College Conditions, Conditions since Graduation, if dead, the Cause and Date of Death, Special Statements. Nothing of importance seems to have been omitted, as to the graduates. But we see no evidence that measures are to be taken for obtaining *the number of students who have been compelled to leave college on account of failing health*, and the proportion it bears to the whole number of students. This is one point as to which there has been so much criticism that we think it ought on no account to be omitted.

One other point is of the utmost importance: *The results must be stated with absolute accuracy, no matter which side they may favor.* Theories must yield to facts. Dangers to health must be uncovered and remedied, if they exist, or, if falsely asserted, it must be so stated upon a firm foundation of facts. "*Mehr licht*" is what we want, and it seems we are going to get it.

THE APPLICATION OF RESORCIN IN THE TREATMENT OF CHANCRE.

DR. LEBLOND has recently employed, in his service at St. Lazarus, as a topical agent, resorcin, in the treatment of chancre, mucous patches, urethritis, and vaginitis. As regards soft chancre, Dr. Leblond finds that resorcin is more efficient in securing cicatrization of a soft chancre than iodoform, and the duration of the treatment is shorter. It is the more desirable in these cases, since it is free from odor, and does not cause any symptoms of toxæmia, even when used in considerable quantity. The local effect of resorcin, when applied to a fresh wound, is caustic, but the action is very superficial; the surface is whitened because of the coagulation of the albumen, but the parts beneath are unaffected. If a pinch of resorcin, moistened, is placed on the lips, a whitish spot of vesication is produced, but the effect is limited to the epithelium.

By Dr. Leblond, for the purposes above indicated, resorcin is applied in powder, and also in solution. The solution is prepared by dissolving resorcin in the proportion of twenty-five per cent. in distilled water. The application of this is made by suitable dressings three or four times a day. When pure resorcin is employed, it is thoroughly dusted over the affected surface. The pain is not severe, and soon subsides. The first contact is accompanied by smarting, and resorcin, which is so closely allied to carbolic acid, does not have the same power to lessen the irritability of the sensory nerves.

Take it all in all, resorcin is a promising substitute for the offensive, if efficient, iodoform. If Dr. Leblond's observations are confirmed we have a valuable resource in this remedy. As its production is not difficult and its cost comparatively low, there seem to be ample reasons for its employment.

THE CHILDREN'S COUNTRY WEEK.

WE have before us the Sixth Annual Report of the Association thus appropriately named. It is most delightful reading, partly because it is short, partly because it details such practical religion, and not least because the subscription list covers more pages than the report itself.

Few charities are more deserving of hearty support. Like the poor, the children we have always with us, and doctors are the very ones who appreciate most of all the physical as well as the higher benefits to be derived from such a change as a week in the country. To many of the little sick folk in whom our drugs can oftentimes work but little change, God's pure oxygen, the green fields, the barn, and the hay-mow are the tonics to fill their bloodvessels and tan their cheeks.

The Philadelphia Association gave over 1800 persons an average of nine days in the country, and nearly 17,000 were sent on day excursions. The average cost the previous year was twenty cents for the latter and $2.20 a week for the former. The economy of administration is marvellous, as it was only four and one-half per cent. of the receipts!

After a careful personal inspection by a committee, thirty-five boarding-houses were selected to supplement the too scanty private invitations. Usually these were respectable farmers who received from four to six boarders each. All of the children were inspected to see that they were free from contagious disease, and as far as possible of good personal character; and each small child was labeled with a tag bearing its home address and destination, while postal cards properly addressed were provided so that the Association and the parents were informed of its safe arrival. Each child, also, was met on its return by a proper escort.

We call the attention of the profession to this charity, that they may avail themselves of it for the suffering little folk in the approaching summer, and also, that they may commend its treasury to their friends.

SOCIETY PROCEEDINGS.

THE AMERICAN MEDICAL ASSOCIATION.

Thirty-fourth Annual Meeting, held at Cleveland, Ohio, June 5, 6, 7, and 8, 1883.

(Specially reported for THE MEDICAL NEWS.)

(*Concluded from page 663.*)

GENERAL SESSION.

FRIDAY, JUNE 8TH, FOURTH DAY.

THE Association was opened with prayer by the Rev. Chas. Terry Collins.

First in order were

AMENDMENTS TO THE CONSTITUTION.

DR. N. S. SMITH, of Dakota, offered an amendment to the Constitution to the effect that two delegates should be received from the Medical Department of the Indian Bureau; these delegates to be nominated each year by the Surgeon-in-Chief of the Bureau, and appointed by the Secretary of the Interior.

The amendment was laid on the table.

The Secretary read an amendment offered by Dr. Toner, the purpose of which was to abandon the office of Permanent Secretary.

DR. TONER arose, however, and withdrew the amendment, because he had learned that the salary of the Secretary was an honorarium, and as the establishment of the Association Journal relieved that officer of the duty of editing the volume of Transactions, the Association would be saved that expense without the passage of the amendment he proposed.

The amendment of DR. J. H. SEARS, of Arkansas, providing that the Chairman and Secretary of any Section may at any time add to their number such recognized and able workers in addition to those named by the Nominating Committee, received strong opposition, and was laid on the table.

The Secretary being requested to read the amendment offered with regard to the admission of new members, Dr. Toner stated that in the opinion of the Judicial Council none of the methods proposed for the admission of members were wise or expedient, and that therefore the amendment had been withdrawn.

DR. J. W. SMITH, of Iowa, offered as an amendment that the words, "without the right of voting," be stricken from the clause respecting permanent members.

DR. N. S. DAVIS spoke at some length upon the impropriety of such an amendment. He said it gave any man the right, no matter how unfit his abilities or how incapable of becoming a delegate from his home Society by reason of any misdemeanor, dishonesty, or indebtness, to come to the meetings of this Association and by paying his dues there vote upon all questions, and he was confident the end would be disastrous. Further, he said, he was confident that there was not now a permanent member present who would insist upon the passage of this amendment, if he but allowed himself to consider all the important principles it involved.

The resolution was indefinitely postponed.

Next in order was the

REPORT OF THE JUDICIAL COMMITTEE,

which was read by Dr. N. S. Davis,

In regard to the petition of Dr. D. W. Day, asking for a rehearing of his case, which was adjudicated last year, the Council ordered the return of the petition to Dr. Day, with leave granted to supplement said paper by a written statement of the character of the new evidence which he proposes to introduce, and the Council decline to act upon the case until the opening of the session next year, from the impossibility of notifying all the parties concerned.

IN THE CASE OF DR. D. H. GOODWILLIE, OF NEW YORK, who signed *under protest* the clause of submission to the Code of Ethics printed upon the registration blanks, the Council decided that the registration of Dr. Goodwillie be cancelled, and the annual dues be returned to him.

The report was accepted and the recommendations adopted.

EXAMINATION OF RAILWAY EMPLOYÉS.

DR. FOSTER PRATT, of Michigan, offered a resolution that the Legislature of each State be petitioned to enact a law at their next annual session, to require all railroad employés to be examined as to the hearing of the watch, voice, bell, and whistle, before being admitted to railroad service.

A resolution was offered also, petitioning Congress to provide means for securing a more efficient

MEDICAL ATTENDANCE ON OCEAN STEAMERS.

A committee was appointed for this purpose, consisting of Drs. A. N. Bell, New York; A. L. Gihon, U. S. Navy; J. N. Quimby, New Jersey; H. O. Marcy, Massachusetts; and H. H. Smith, Pennsylvania.

CLASSIFICATION OF PAPERS.

DR. A. N. BELL then introduced the following resolutions:

Whereas, The practice prevails of reading papers before the several Sections at the option of their authors, without sufficient regard to the special objects for which the Sections were created, therefore,

Resolved, That all papers hereafter offered or intended to be read before the Association, or any of its Sections, except the Addresses of the president and chairmen of the sections, shall be first referred to the trustees of the *Journal* for classification and appropriate references.

An amendment to refer these resolutions to the Committee of Arrangements was proposed by Dr. Toner, and lost, and the original resolutions were then adopted.

DR. BRODIE, of Michigan, introduced the following resolutions

ON THE DEATH OF SURGEON-GENERAL BARNES:

Whereas, The Association takes a deep interest in the efficiency of the Medical Department of the United States Army, and

Whereas, The late chief of the Department, Surgeon-General Joseph K. Barnes, contributed largely to the efficiency of this Department in the work which it has been and is doing for medical science and education, therefore

Resolved, That the Association receives with profound regret the information of the death of General Barnes, and desires to record its appreciation of the great value and importance of the work which he has done, and enabled others to do for the advancement of medical science.

Resolved, That this Association recognizes the energy and ability which characterized the administration of General Barnes and his services in connection with the Army Medical Museum and Library and publication of the *Medical and Surgical History of the War*, and other works of great value to the profession.

Resolved, That a copy of these resolutions be sent to the Surgeon-General of the Army.

These resolutions were adopted and ordered spread upon the minutes.

CREMATION.

DR. J. M. KEILER, of Arkansas, offered a resolution that in the very near future, if not now, cremation will become a sanitary necessity in the large cities and populous districts of the country. Referred to the Committee on Hygiene.

When the *Address on Diseases of Children*, to be delivered by DR. R. M. BLOUNT, of Indiana, Chairman of the Section, was called for, it was found that he had left the city, and had made the request that his paper be referred without reading to the Publication Committee, and it was so referred.

DR. QUIMBY, of New Jersey, offered a

RESOLUTION OF THANKS

to the citizens of Cleveland for their unlimited kindness in the manner in which they have received the delegates and entertained them during their stay.

Unanimously adopted.

ADDRESS OF THE RETIRING PRESIDENT.

THE PRESIDENT, DR. JOHN L. ATLEE, of Pennsylvania, then arose and said:

GENTLEMEN OF THE ASSOCIATION: In retiring from the chair to which you have elected me, I had hoped to have the pleasure of introducing to you my successor. But I assure you that it is with great satisfaction that I transmit the place to him, for he is a gentleman worthy of it; a gentleman who has done as much for the medical literature of the country as almost any other one, and one whom I characterized a few days ago as the Lænnec of America. I thank you for the support you have given me, and I can only ask that you forgive my shortcomings. I bid you an affectionate farewell.

He then introduced the Second Vice-President, Dr. Lester, in the absence of Dr. Austin Flint, who had been called to New York the night before.

THANKS TO DR. ATLEE.

DR. GARCELON, of Maine, offered the following:

Resolved, That the thanks of the American Medical Association be extended to the retiring President, Dr. Atlee, for the able, dignified, and satisfactory manner in which he has presided over the deliberations of this assembly; and that he retires with the best wishes of every member of this Association for a long continuance of a life so highly useful not only to the present but to all future generations.

Unanimously adopted.

The Association then adjourned, to meet in Washington, D. C., on the first Tuesday in May, 1884.

EXCURSION.

In the afternoon the delegates remaining in the city with their wives, in all about six hundred, were conveyed by a special train over the Nickel-Plate Railroad to the elegant residence of Mr. and Mrs. D. P. Eells, at River Bank, a beautiful little promontory on Lake Erie at the outlet of Cuyahoga River. After an hour or two of rambling through the grove and viewing the lake, refreshments were served, and the guests were again returned to the city in time for the evening trains over the various railroads.

SECTIONS.

SECTION OF PRACTICAL MEDICINE, MATERIA MEDICA, AND PHYSIOLOGY.

WEDNESDAY, JUNE 6TH, SECOND DAY.

DR. THOMAS N. REYNOLDS, of Detroit, read a paper on

THE ALIMENTARY CANAL IN BRONCHITIS AND PHTHISIS.

He said that the abnormal condition of the alimentary canal and portal and lacteal systems was often the predisposing cause of both acute and chronic affections in all parts of the respiratory apparatus. Speaking only of bronchitis and phthisis, acute tracheobronchitis was often caused by excess in diet, with proportionately incomplete elimination. In view of this fact, the treatment should be prompt, and include evacuation of the bowels and restriction of the diet to a light liquid form. Necessary quiet and warmth of the surface should be maintained, but the atmosphere of the room should not be too warm. The cathartic, hot drinks, and a warm surface produced a revulsion of nervous energy from the inflamed part to the bowels, kidneys, and skin. He deprecated the use of ordinary cough mixtures to the exclusion of this more rational treatment. Morphine, quinine, aconite, and veratrum viride were the more usually appropriate remedies in the first stage, but did not equal the treatment without drugs to which he referred.

Catarrhal and fibroid phthisis most frequently were the result of neglected chronic bronchitis, and should be treated in much the same way, not by cod-liver oil or any other supposed specific alone, especially if they interfered with digestion; but quinine was useful in lowering temperature and lessening the secretion of pus, and the patient should cultivate an out-door life with plenty of physical exercise and wholesome mental occupation. Under this regime, digestion and tissue-building soon went on properly, cavities often healed, and recovery became complete. Any region free from malaria or unwholesome emanations, with a temperature permitting constant out-door life, would answer for a resort. Tubercular phthisis had sometimes seemed to be excited by neglected bronchitis in those of tubercular family history and of constipated habit and general defective elimination, and who lived an inactive in-door life.

In dyspepsia, with constipation and septic fermentation of the ingesta, it seemed probable that the septic products might be carried by the portal and lacteal vessels direct to the capillaries of the lungs, and be there sometimes auxiliary in causing bronchitis and phthisis in any or all of their forms.

DR. BELFIELD, of Illinois, then read a paper on the *Germ Theory of Disease, with Micro-photographic Illustrations*; and DR. SHOEMAKER, of Pennsylvania, read a paper on *Mechanical Remedies in the Treatment of Skin Diseases.*

DR. L. B. TUCKERMAN, of Ohio, followed, with a paper on a

NEW METHOD OF OBTAINING PURE PANCREATIC JUICE.

Until lately there have been but two methods of obtaining pure pancreatic juice, that of Bernard and that of Ludwig, both of which are open to objections, and the author was not disposed to admit that fluid collected under these circumstances represented the normal fluid. He had recently obtained the pancreatic juice by means of a permanent fistula in the pancreatic duct of the dog. It is decidedly alkaline, perfectly transparent, and less viscous than that obtained by Bernard. But he has not yet made a complete chemical analysis of it.

THURSDAY, JUNE 7TH, THIRD DAY.

DR. J. SOLIS COHEN, of Philadelphia, read a paper entitled

THE ELEMENTS OF PROGNOSIS AND THERAPEUTICS IN LARYNGEAL TUBERCULOSIS.

Dr. Cohen commenced by stating that while admitting the fact that the prognosis was always bad, it might be maintained that it was much less unfavorable in certain classes of cases than in others, and that the indications of the probable length of life could be predicted in great measure from the laryngoscopic picture.

Intense pain in swallowing supervening upon an acute laryngitis, the result of sudden exposure, was the most prominent subjective local symptom in acute tuberculosis of the larynx. Laryngoscopy revealed the cause of the painful dysphagia in great tumefac-

tion of the epiglottis, soon followed by ulceration of this structure and of the fold of tissue uniting it with the pharynx. The duration of the disease, which always terminated fatally, varied from six weeks to six months as the rule. The most efficient means of relief was afforded by insufflations of morphia, or of morphia and iodoform. Previous to the insufflations, the secretions should be detached by the propulsion upon the parts of some alkaline spray. The formula most used by the writer consisted of five grains of borate of soda dissolved with one drachm of glycerine and seven drachms of tar water.

The chronic form of tuberculosis might be divided into two chief groups, one of which lasted from six to eighteen months, and the other from two to four years or more. Congestion of the larynx early in pulmonary tuberculosis, followed by infiltration of the epiglottis, and its progressive destruction by ulceration, is indicative of the more rapid process. Pallor of the mucous membrane, succeeded by tumefactions at the posterior portions of the larynx, is indicative of the slower process. Infiltrations of the interior of the larynx indicate a still slower process in many instances, and ulcerations limited to the epiglottis indicate a much more rapid one. The interference with deglutition is a marked factor in the downward progress of the disease.

With regard to therapeutic measures, in addition to the constitutional treatment appropriate to pulmonary tuberculosis, much good may be done locally by keeping the parts cleansed with alkaline spray, and painting the intumescent parts with equal parts of compound solution of iodine and glycerine, or weak solutions of iodine and carbolic acid combined. In the stage of ulceration, nothing seems to act so well as insufflation with well-powdered iodoform, the unpleasant odor of which may be tolerably well masked by rubbing with it a little attar of rose, one minim to the drachm, or essence of rose geranium, three or more minims to the drachm.

Careful medical attention in this way, with due regard to intercurrent requirements, renders the condition of the patient much more satisfactory, and even starts one now and then on the actual road to recovery.

DR. H. A. MARTIN, of Massachusetts, then read a paper on

VACCINATION AND PROPAGATION OF VACCINE VIRUS,

in which he claimed that the proper sources of vaccine are young heifers which have not dropped a calf. The young animal is perfectly exempt from diseases to which the older animals are subject; tuberculosis, for instance, which, in the bovine species is extremely difficult to check, is a disease of old animals; and recent discoveries make it appear that virus from a tuberculous animal is unsafe. Young animals, then, from four to eight months old, are to be preferred. After vaccination they are ready to yield the virus in from six or eight days. A physician must then determine when the vesicle is in the right state to yield lymph, and when the pressure is to be applied. The epidermis of the heifer is very tough and resistant, and does not yield the virus as readily as the human arm. At each point where a puncture is made a drop of perfectly pellucid lymph appears, and upon the application of pressure, it pours forth in a quantity that is surprising. The first points covered are so bloody that we do not use them, yet a large proportion of the points collected are bloody. The number of quill-points collected from a single animal varies from two thousand to six thousand. There being a limit to the production; there must be a minimum price for which the virus can be produced. If you vaccinate an animal once, it can never be vaccinated again.

DR. J. H. HOLLISTER, of Illinois.—If you vaccinate in two places, will you not obtain twice as much virus as when you vaccinate in one?

DR. MARTIN.—Yes.

DR. HOLLISTER.—Then why can you not increase the number of vaccinations indefinitely, and so obtain a larger amount?

DR. MARTIN.—Because the external area of the calf is limited. There are only limited portions of the calf that are fit for vaccination. I have found that the buttock is altogether the best part of the animal for this purpose. We vaccinate in from sixty to one hundred and twenty places.

DR. A. T. KEYT, of Cincinnati, then read the closing paper on the *Diminution of the Retardation of the Pulse in Aortic Insufficiency.*

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

WEDNESDAY, JUNE 6TH, SECOND DAY.

DR. JOHN MORRIS, of Baltimore, read a paper on

WHAT MEANS CAN BE JUDICIOUSLY EMPLOYED TO SHORTEN THE TERM AND LESSEN THE PAIN OF LABOR?

He said that in no one thing have the wisdom and genius of the age been more thoroughly exhibited than in the advance and elevation of the art of midwifery. Once considered an inferior branch of medicine, it has, through the vigor and enlightenment of those pursuing it, risen to the highest rank in the scale of the sciences. He confined his remarks to the management of natural, uncomplicated labor. He treated cases of lingering labor, which he divided into three stages or conditions: 1. Labor may be lingering when the head is delayed at the brim of the pelvis. 2. Where the os has dilated to some extent, and the head has descended into the vagina. 3. Where it has reached the vulva, and impinges on the perineum.

When labor is tardy in the beginning, the os dilating very slowly, the pains feeble and irregular, and the head high up, means may be carefully employed to hasten its progress; but if the woman is cheerful and hopeful, interference may be delayed, but not for twelve or sixteen hours, as Churchill and other writers have recommended. Exhaustion of the woman's powers in the first stage necessitates instrumental aid in the second.

In cases of slow dilatation, Braun, of Vienna, recommends the introduction of an elastic catheter between the chorion and the walls of the uterus; but Dr. Morris thinks the cautious use of the finger much better. After detachment of the membranes in this way, if the soft part of the finger is pressed gently around the whole margin of the os, stretching it, the bag of waters will commence to project, the os will dilate, and the pains become effectual.

For painful cases, where the membranes rupture prematurely—tardy dilatation, due to rigidity; spasmodic contraction; that condition of the uterus in which the fibres of the cervix contract, and form a rim or band above the os; inertia; rigidity of the perineum, etc.; the means the author suggested were detachment of the membranes, dilatation of the cervix, administration of opium or chloroform, hot-water douches, the colpeurynter, dilatation of the perineum by manipulation, sweeping the anterior lip of the os over the occiput, but, above all, forcible external compression. In case all these means fail, the only resource is the forceps, and their application should not be delayed. Dr. Morris strongly recommends Beattie's straight Dublin forceps when the head presents itself at the outlet. He stated in conclusion that, in making these suggestions, he did not wish to be understood as recommending an imitation of the *lesser labors* of the French, where the accoucheur, with

rolled-up sleeves, presents himself in front of the patient, and, with great flurry and a show of manipulation, leads the bystanders to believe that he himself is doing the parturient work, but a scientific employment of measures which experience has proved to be both rational and useful in furtherance of the greatest physiological process known to man.

DR. T. A. REAMY, of Ohio, said that if there was anything that was an abomination, and ought to be banished from obstetrical practice on account of its great danger to the mother and child, it was ergot. (Applause.)

DR. E. C. DUDLEY, of Illinois, then read a paper on

THE IMMEDIATE APPLICATION OF SUTURES IN PUERPERAL LACERATION OF THE CERVIX AND PERINEUM.

He said that the examination of several hundred cases of immediate perineorrhaphy showed the deeper perineal structures had not satisfactorily united except in a very few cases.

1st. This is accounted for by the failure of operators to include the deep muscular and connective-tissue structures in the suture; to use a sufficient number of sutures; to use silver sutures, to bring the parts accurately together, to pass the sutures at right angles to the laceration, and to continue therein throughout the vaginal portion of the rupture, as well as throughout the cutaneous portion.

2d. Even when these precautions had been observed and complete union had been secured, subsequent examinations often show that the perineum is too small to fulfil its functions.

3d. To insure a permanent perineum of normal size the operator should denude a strip entirely around the ruptured surfaces about one-quarter of an inch in breadth. In consequence of this the perineum, although somewhat larger than normal immediately after closure, will subsequently contract to its proper size. This denudation also serves the important purpose of insuring union by first intention, because it fortifies the torn surfaces by smoothly denuded surfaces which have a greater tendency to adhere. The objection so often raised against the immediate suture, that it so often fails of union, is obviated, and the immediate operation, thus modified, becomes as certain in its results as the secondary operation. This paper elicited some discussion by Drs. Harvey, of Ohio; Watkins, of Kentucky; Jenks, of Chicago; Morris, of Baltimore; Ulrich, of Pennsylvania; and Parsons, of Detroit.

DR. WM. H. TAYLOR, of Ohio, then reported a case of *Gastro-elytrotomy*.

THURSDAY, JUNE 7TH, THIRD DAY.

DR. P. ZENNER, of Ohio, read a paper on the

VALUE OF GYNECOLOGICAL TREATMENT IN HYSTERIA AND ALLIED AFFECTIONS.

He said that lesions of the female genitalia are sometimes productive of hysteria or allied affections, and that the removal of the local lesion sometimes alleviated or cured the nervous disease.

Hysteria is a disease of the nervous system involving the great nervous centres. It may be termed a functional disease. That a peculiar condition of the nervous system underlies the development of hysteria is seen in the fact that it usually occurs in individuals predisposed to such affections.

The predisposition alone seems sometimes sufficient for the development of the nervous malady; though some exciting cause calls forth its first manifestations. Most frequently this is of psychic origin, emotional excitement, fright, or the slower action of some strong and absorbing passion. Not uncommonly, the exciting cause appears to be some peripheral source of irritation, producing the disease in a reflex way.

A close relationship between genital functions and nervous diseases is seen in the frequent development of the latter at important periods of sexual life. The time of puberty and the climacteric period are especially favorable for the outbreak of nervous diseases. The periods of gestation and lactation have, though less frequently, a similar record.

It is undoubtedly a fact that hysteria and uterine disease very frequently occur together. But we must not hastily conclude that one is dependent upon the other; perhaps this is a mere coincidence.

It is no uncommon thing to see uterine lesions disappear without improvement of the nervous symptoms, as also the cure of the nervous disease, while the lesions in the genital organs remain.

Dr. Zenner then cited a case, reported by Rosenthal, of hystero-epilepsy, where the unsexing of the woman had no influence on the hysterical seizures, and also a few cases that were under his own care. He added, there are no other diseases which cause the mind to dwell so persistently on the diseased organ as those of the genital organs, and in such cases the influence of the mind is especially injurious. It is important in the treatment to divert the thoughts from the genitals as much as possible. Also, we cannot too strongly condemn the promiscuous gynecological examination of girls or unmarried women merely because there are nervous symptoms.

In the mean time, it must be remembered that the general treatment, the toning up of the nervous system, is always the most important object. In fact, the duty of the physician demands much more than the mere treatment of existing manifestations. He should attempt to prevent the disease, to eradicate the predisposition upon which it depends. He must warn society that the idle lives of the fashionable ladies, with just such employments or amusements as heat up an already wayward imagination, or foster the morbid feeling in their nature, must produce hysterical affections in them, just as overwork, intense application to business, and, even more, the unfortunately common habits of gambling, lead to immense mental injury to men. The physician should inculcate the practice of proper hygienic regulations in childhood, point out a system of education that will soundly develop body and mind, and lead to habits of self-control and unselfishness.

When the disease already exists, proper moral, hygienic, and constitutional treatment, hydrotherapy, etc., and in obstinate cases the plan of treatment brought forward by Weir Mitchell, will often lead to happy results.

This paper was discussed by Drs. Reamy, of Ohio; Garcelon, of Maine; Catlett, of Missouri; Maughs, of Missouri; Proctor, of Illinois; Reed and Zenner, of Ohio.

The CHAIRMAN announced as a *Committee for the Selection of Subject for Prize Essay*, Drs. L. F. Warner, of Massachusetts; H. D. Didama, of New York; and W. H. Byford, of Illinois.

The Committee of Award, was appointed by the Chair as follows: Drs. J. C. Reeve, of Ohio; T. A. Reamy, of Ohio; G. M. B. Maughs, of Missouri.

DR. G. M. B. MAUGHS, of Missouri, read a paper on *The Midwifery and Gynecology of the Ancients*.

DR. H. A. MARTIN, of Boston, then read a paper on

AN APPLIANCE ADAPTED TO OCCASIONAL GYNECIC AND OBSTETRIC EMERGENCIES.

This is a thin bandage of pure rubber, nine inches wide and from five to six feet long, and has been found of very great value in many cases of abdominal dis-

ease in which no other form of bandage could be endured by the patient.

Section on Surgery and Anatomy.

Wednesday, June 6th, Second Day.

Dr. Robert Newman, of New York, presented a paper on the *Surgical Use of Electrolysis*, in which he submitted a tabulated statement of one hundred cases of urethral stricture treated by this method.

Dr. James R. Taylor, of New York, then read a paper on the

TREATMENT OF FRACTURES OF THE LONG BONES,

in which he briefly presented some methods of diagnosis and treatment from the extensive surgical *clientèle* of the out-door department of Bellevue Hospital. He first spoke of fracture of the thigh bone, which he treats with a saddle made to fit into the perineum, whereby he secures the most perfect comfort possible by any apparatus used for the purpose of counter-extension. This neatly devised little saddle is held in position by a strap, running to the headboard on each side, thus securing the patient in an immovable position. By fastening strips of adhesive plaster, previously secured to the leg, to a screw arrangement in the foot of the bed, he can produce any desired degree of extension of the limbs by simply turning the little screw at the foot of the bed; the chief advantage of the whole apparatus over all other instruments being the little saddle on which the patient sits, as it were, with comfort, he claims, rather than misery, as in most other methods. He announced himself as positively opposed to the old method of using stones and other suspensory weights to produce extension of the limbs, and then turned his attention to the treatment of fractured ribs. He brings the broken ends into place by raising the arms over the head, an original method by which he claims there is no trouble in adjustment. They are then held in place by a band of adhesive plaster around the body.

Dr. H. O. Marcy, of Massachusetts, presented an experimental study of the *Comparative Value of Antiseptics*, in which he summarized the results of his experiments with alcohol, boracic acid, carbolic acid, bichloride of mercury, bichromate of potash, naphthaline, balsam of Peru, common salt, turpentine, glycerine, iodoform, and other germicides. He expressed the hope that Dr. Sternberg would be appointed to make further experiments, and that suitable aid would be furnished him for carrying on an elaborate scientific investigation in this promising field.

Dr. Lewis Hall Sayre, of New York, next read a paper on

AMPUTATION BELOW THE KNEE-JOINT IN PREFERENCE TO "BRISEMENT FORCÉ," OR RESECTION, IN CERTAIN CASES OF DEFORMITY WITH ANCHYLOSIS, ILLUSTRATED BY TWO CASES.

He said that certain diseases of the knee-joint, unless treated with proper extension and counter-extension, result in more or less deformity, consisting of flexion and luxation of the leg backward, in which situation the limb may become fixed or solidified. If anchylosis is fibrous, it can be broken up, and use of the limb and joint frequently follows. If the solidification is bony, and the leg of the same length as the other, a V section should be made through the angle of deformity and the limb straightened and anchylosed in this position. But in cases where disease of the joint has occurred in early life and resulted in bony anchylosis and deformity, the limb below the joint grows more slowly than the other, and as after a V section through the bone, the limb does not grow, by the time the patient reaches adult life it becomes so short as to be practically useless. In these cases amputation below the knee-joint is preferable when performed by a modification of Prof. Smith's amputation at the knee-joint, Dr. Sayre preferring to saw through the head of the tibia rather than disarticulate at the joint.

Dr. Sayre cited two cases occurring recently in his own practice, in which he had made successful amputations below the knee-joint. One was performed eight weeks ago, and the patient is now walking on an artificial limb; the other, two weeks ago to day, and the limb was dressed for the last time last Sunday.

Dr. E. M. Moore, of New York, read an interesting paper on the

TREATMENT OF OLD CASES OF COMPOUND DISLOCATION OF THE ULNA IN CONNECTION WITH COLLES' FRACTURE.

In cases of fracture of the radius, known as Colles' fracture, there is also a dislocation of the styloid extremity of the ulna, which dislocation in many instances is not reduced and great deformity is the result of the fracture. In cases brought to him before the expiration of six months, Dr. Moore does not hesitate to re-break the united fracture, and attempts a reduction of the dislocation; but when the case has gone so long as not to permit of re-fracture, he exsects the extremity of the ulna, thus making a movable and useful joint. He narrated the details of several cases in his own practice.

Dr. Hyde, of New York, bore strong testimony in favor of the position taken in the paper, and said that the method of Dr. Moore was the only way he knew to cure the deformity.

Dr. Quimby, of New Jersey, said that, in his practice in cases of Colles' fracture, he had always used the straight splint, and had never had a single bad result, either in young or old.

Dr. V. H. Coffman, of Nebraska, next read a paper on *Treatment for Tender Spines by Subcutaneous Incision.*

Thursday, June 7th, Third Day.

Dr. W. A. Byrd, of Quincy, Illinois, read a paper on

EXCISION OF BOTH HIP-JOINTS FOR MORBUS COXARIUS.

He said that, ever since the first suggestion of the removal of the head of the femur by Charles White, in 1769, for morbus coxarius, there has been great diversity of opinion in regard to the propriety of this operation, a few favoring it, but many condemning it as entirely useless. For while it might save the life of the patient it frequently left a miserably deformed being, incapable of locomotion without the aid of crutches or cane, and the chances of cure were no better than if the patient were left to depend upon the slow process of spontaneous exfoliation of the diseased bone—a process rarely accomplished before the death of the patient. Opinions, however, have greatly changed since the number of excisions have become numerous enough to compare with older methods. Dr. Byrd had been able to find a record of but two cases of double excisions. The patient, aged ten years, upon which he operated now goes without crutches up and down stairs and over smooth ground, though using crutches over rough ground. He read an account of her condition previous to the excision, written by Dr. Moses F. Bassett, April 12, 1881. Dr. Byrd removed the head and upper portion of the right femur, commencing the incision two inches above the great trochanter, and continued it downward, curving it so as to pass behind the great trochanter, ending five inches below its origin. The soft parts were pulled aside and detached carefully with the periosteum, from the bone, with a dental scraper. The head of the bone was thrown

out through the opening, and, on account of the softened condition of the bone, it was divided just below the trochanter with pliers. There being an abscess over the greater trochanter of the left limb, it was freely laid open, and the trochanter removed with the pliers, there appearing to be no other portion of the bone diseased. Both wounds were dressed with balsam of Peru and oakum, and the child placed in one of Dr. W. P. Verity's splints.

DR. VERITY, of Chicago, here exhibited his splint and derrick, and explained their operation. He placed upon the platform an upright post, to which he attached a triangular frame, made of strips of wood fastened together by strong strap-iron hinges, and attached to the upright by means of a clamp. From the extremity of this triangle hung suspended, by a strong cord, the wire framework in which the patient lies, capable of adjustment to fit any desired position of the limbs. The triangular frame can also be adjusted at an angle, and is capable of being attached to a door post, or any such convenient upright. The entire apparatus is very portable, and can be packed up for transportation in a few seconds; while in this condition it occupies no more space than an ordinary violin box. Dr. Sayre, of New York, and Dr. Gunn, of Chicago, spoke in high terms of the splint.

DR. HENRY O. MARCY, of Massachusetts, next read a paper on the

SURGICAL TREATMENT OF INTESTINAL OBSTRUCTION.

He said that intestinal obstructions may well be subdivided into—

1. Chronic, which is gradual;

2. The late acute, which usually supervenes upon the first; and,

3. The early acute.

Under these divisions are included impaction of feces, fibrous and cancerous strictures, polypi, tumors, abscesses compressing the bowel, intussusception, and injuries; but we shall discuss now only the question of acute obstructions.

The first and most important consideration is not only an accurate, but a prompt diagnosis. Internal obstructions should be relegated to the surgical domain, upon precisely the same grounds as external obstructions. Granted that diagnosis of complete internal obstruction has been determined, the earlier operative interference is decided upon the better. In intussusception the old Hippocratic plan of inflation may be tried, and this is much more likely to succeed under anæsthetics. Dr. Thomas Hawkins, of New York, strongly advocates hydrostatic pressure. Early recourse should be had to gastrotomy, under the most careful antiseptic precautions.

Finding the obstructed portion, be guided by its factorage. If there are long bridles of peritoneal bands, then simple division may be all that is required. If a twist or intussusception, perchance these are easily remedied. What shall be done if necrosis of the intestinal tube has already supervened? One of two devices only is left for selection, *i. e.*, stitching the ends of the canal into the wound, with the hope of some further operative procedure, or resection of the necrosed portion, with very careful adjustment of the divided ends and mesenteric attachment. This must be done in such a manner as to bring the peritoneal surfaces in approximation, and in this way the wounded edges and mucous membrane are all turned into the intestinal cavity. Silk may be used, but properly prepared animal ligatures are to be preferred. Having restored the continuity of the intestinal canal, close the abdominal wound. This is effected precisely as in ovariotomy, with careful antiseptic precautions.

DR. GARCELON, of Maine, asked Dr. Marcy what his experience had been in abdominal section for intestinal obstruction, so far as good results were concerned.

DR. MARCY replied that his experience had not been very large, but some cases had been fatal, others successful in their outcome.

DR. MOORE, of Rochester, said that in making an operation for removal of any intestinal obstruction, he did not use the carbolic-acid spray, but was in the habit of pouring carbonic-acid gas into the cavity, believing the true theory to be not to cure the atmosphere but to keep the atmosphere out.

The paper evoked considerable discussion on the relative merits of aseptic and antiseptic treatment, which was participated in by Drs. Byrd, Murdoch, Keller, Moore, and Marcy.

DR. T. F. PREWITT, of St. Louis, next read a paper on

A NEW OPERATION FOR THE CURE OF RANULA.

He said: The methods recommended and practised by surgeons at this day consist either in the introduction of a seton, injections into the sac, or partial excision of the ranula. Of these, almost all modern surgeons prefer excision of a portion of the sac, total excision being impracticable. Having met with a case of double ranula recently, in which this partial excision, followed later by persistent catheterization, failed, it occurred to me that I might, by a plastic operation, secure a permanently patulous orifice.

Case: Fifteen years old; swelling under left lower maxilla nearly as large as a goose egg; fluctuated freely, some portions seeming hard, and projected into the mouth under the tongue. Diagnosis of ranula was made, and a portion of the cyst-wall in floor of the mouth was excised. A quantity of clear mucoid fluid spurted out as the cyst was incised. In the course of two or three weeks this had contracted and threatened to close, and catheterization was resorted to. In the mean time, a ranula had appeared under the tongue upon the right side, with translucent, bluish, thin walls, but not projecting beneath the jaw. This also was treated by excision of a portion of the cyst-wall.

In July the young man ceased to present himself; the orifices had closed, the sacs rapidly filled, and he was again brought to me in an alarming state from threatened suffocation. Both ranulæ were swollen and painful. Upon the left side, the swelling extended well down toward the clavicle and sternum and across the trachea in front. Upon the right side, the ranula was greatly swollen, meeting with that upon the left side under the chin in a continuous swelling from the angle of the jaw upon one side around to the opposite side. Both inspiration and expiration were obstructed, the patient was flushed and feverish, and it seemed as if tracheotomy might be necessary. I incised the cysts freely, permitting the escape of the accumulated fluids, and directed hot fomentations to be persistently applied. This gave speedy relief to all urgent symptoms, and as contraction took place, I then resorted to catheterization, with the view of preventing reclosure. This was persevered in for two or three months, and was more effectual upon the left side, for the reason that the bougie—a soft conical rubber, about No. 15 French—could be passed down for two inches, and could be felt below the margin of the jaw upon the right side; and when its use was intermitted for a few days, the opening would close completely. I determined, therefore, to make a permanent opening by a plastic operation on that side. I carefully dissected the mucous membrane of the mouth over the cyst, denuding a surface as large as a nickel. I then incised the cyst-wall, turned it over, tacked its free edge to the border of the mucous membrane of the mouth with fine silk sutures;

union by first intention took place; the stitches were removed upon the third day, and an orifice was secured that has remained patulous to this time. This was in November last; the patient became irregular in his attendance, and finally ceased to present himself to have the left side catheterized. On the first of April he came to me with considerable accumulation on the left side, and the orifice closed. I repeated the operation on that side with a like fortunate result, and now the openings are patulous upon the right and left sides, and the patient has no trouble whatever from reaccumulation of the fluid.

DR. JOSEPH RANSOHOFF, of Cincinnati, next read an elaborate paper on

THE EARLY USE OF THE TREPHINE,

saying that a careful study of the vascular relation of a bone to its periosteum and medulla, led to the conviction that there could be no serious deviation from the normal in either without implication of the remaining parts. He stated these propositions: 1. That the exposure of the medullary cavity *per se* is unattended by deleterious consequences. 2. That the continuance of increased intra-osseous pressure is the main source of secondary changes. If these propositions are correct, it follows that in the very earliest possible use of the trephine, we possess an inestimable means of saving life in the acutest forms of bone disease, of curtailing by months, and even by years the course of others, and of preventing the deformities and operative mutilations that follow in the wake of even mild cases. Dr. Ransohoff gave interesting details of three cases, in which he had used the trephine with good results.

DR. GUNN, of Chicago, expressed very warm approbation of the paper, stating that it perfectly coincided with his own experience, which dated back more than a quarter of a century. He stated that in bone operations he poured into the wound from a teaspoonful to a tablespoonful of boracic acid, which he considered the best of antiseptic agents, and guarded against the too early closing of the bone by inserting pure white wax moulded into forms of suitable size for the opening, frequently boring a hole through the wax, making it essentially a drainage-tube.

DR. HYDE, of New York, also spoke in confirmation of the grounds taken in the paper.

DR. H. J. REYNOLDS, of Mich., next read a paper on

TREATMENT OF STRICTURE OF THE URETHRA.

He said no importance should be attached to the statement of a patient that his stream is of full size. The size may be evidence of presence of stricture, but not of its non-existence. For either large or small calibred stricture he prefered internal cutting and stretching with Otis's instrument to all other methods. He always, however, provided the patient with a full-sized sound, with instructions to pass it every few days for an indefinite length of time. If the stricture be too small for this instrument, he enlarged it sufficiently to admit first, a Thompson's or Maisonneuve's instrument, and then he used the Otis instrument carrying the enlargement even beyond the normal calibre to ensure the absolute and complete removal of all obstructions, without which the cure is liable not to be permanent; the smallest amount of obstruction or contraction remaining, he claimed, will furnish a groundwork for future gleet or contraction, or both.

He then gave a report of several cases treated by different methods, showing the comparative merits of each, among which was a case of extreme stricture involving external perineal urethrotomy without a guide, and in which even the prostatic portion was contracted in its anterior part. In this case, a pocket an inch deep and large enough to admit the finger, extended upward and backward in front of the prostate, the septum between which and the urethra he cut across.

SECTION ON STATE MEDICINE.

TUESDAY, JUNE 5TH, FIRST DAY.

DR. ALBERT L. GIHON, U. S. N., read a paper entitled

MEDICAL EDUCATION THE FUNDAMENTAL FACT IN MEDICAL ETHICS.

He said, superficial observers see in the question which has arisen in the State Medical Society of New York only an attempt to break down the guards which hedge in the kingship of our profession. They have, indeed, proclaimed afar that the time-honored traditions of the guild are to be ignored, and the right hand of fellowship given to the accused unbeliever. A year has passed since this question arose, and the dignified body of which we form a part, evaded meeting the issue face to face. A few voices were raised in explanation, but they were drowned in the cry: "Crucify him, crucify him, he breaks bread with a homœopath!" The august fathers of the Association frowned their displeasure, and the venerable puppets of antiquity were taken down from their dusty niches and displayed to exorcise this new demon of the nineteenth century. Outside the halls animated *ex-parte* statements were circulated, and a thousand delegates went away believing that a few individuals in the city of New York, mainly specialists, for purposes of personal profit were advocating the license to consult and confer with avowed homœopaths—this, and nothing more. Since then the matter has acquired a newspaper notoriety, and it is blazoned to the world as a fact, that the delegates of the State and County Medical Societies of New York have disqualified themselves for association with us, because they have sanctioned the formal recognition of homœopaths in clinical conference, and the popular sympathy of the profession has been aroused against these mercenary innovators. It is, of course, the business of the Judicial Council "to take cognizance of and decide all questions of an ethical or judicial character that may arise in connection with the Association," but every member of the Association has an equal interest with these twenty-one in the inquiry into the causes which have induced some of the most exemplary members of the profession to their course. Is it as alleged, that the Code of Ethics is an antiquated piece of verbosity? Does it really accomplish what it professed? Undoubtedly its purport was the exclusion from professional fellowship of all but those who are entitled to it by their intelligence, education, professional skill and acquirements, and that fearless probity that doth become a man. Has it done this? Does it do it to-day? Are there intelligent, educated, skilful, and upright men in the profession because of the Code, or in spite of it? It is unquestionably true there are no homœopaths in the American Medical Association, but are there any allopaths there? Does it say "brother" only to those who are fit to wear the mantle of the wise physician? These are questions for the Association to ask itself, and primarily it is for the State Medicine Section, in its purview over medical education, to discuss calmly, fearlessly, and thoroughly, and to go with its conclusions and announce them to the Association, however unpalatable or unpopular.

I do not propose at this time any formal criticism or arraignment of the Code of Ethics. Practically, three lines only are the shibboleth which the elect are required to utter—"No one can be considered as a regular practitioner, or a fit associate in consultation, whose practice is based on an exclusive dogma." Prior to this it is stated that "a regular medical education is

presumptive evidence of professional abilities and requirements;" but you may read the fifteen pages of the Code in vain for the definition of what constitutes "a regular medical education," and it is to this I now propose especially to limit my inquiry—whether, while straining at the gnat in the twelfth, thirteenth, and fourteenth lines of section one, article four, we have not swallowed a camel in the other eleven.

Mr. Chairman, the time has come when this Association must be up and doing. A few medical schools have undertaken the reform, but the movement that has been inaugurated, notably by Harvard, will avail little, so long as the Association unconcernedly witnesses and indirectly countenances the wholesale manufacture of doctors elsewhere—by accepting their membership without question of their competence. The time has come when something more than paper bulwarks shall be considered defence for our orthodox stronghold, and paper partitions sufficient to separate the sheep from the goats. The time has come for us to act, and it is eminently proper that the Section in State Medicine shall be the scene of action. The discussion in New York has made it impossible for us to remain indifferent spectators. I trust that no member of this Section has been misled into believing that any of the distinguished men who have taken part in this agitation have asked for anything that involves, in the least degree, any concession to the claims of homœopathy, allopathy, or any other exclusive dogma; that none of them have suggested, advocated, or desired any arrangement that can provide for or permit the joint treatment in any case by themselves and homœopaths, or any other paths. They have, however, claimed the right to give their opinion to any one who asks for it, and is willing to pay for it—to tell any sick person what he thinks of his case, and what he considers ought to be done. In this they give no sanction to the "irregular," whoever he may be, who has sought their advice, even though this irregular may be even wiser than that regular who castrates in orchitis and gives his puerperal woman a Russian bath. The very fact of his advice having been sought is an admission on the part of the irregular that he has done wrong or knows not what to do, and if, as alleged, these irregulars have not sought these consultations, then none will be, and the storm is but a tempest in a teapot. It is for you, however, to determine decisively whether you will place under the ban the man whose only offence has been to say to one of these irregulars, "You are doing wrong;" or will exclude from the ranks of the profession that one of your distinguished colleagues in New York, who, when called in consultation in a case of difficult labor, requiring instrumental interference, did not stop to examine the diploma of the attending physician, but went to work, finding him an exceedingly expert assistant, and learned when the patient had been rescued from danger that he had been coöperating with a homœopath; or will threaten the young road surgeon, who, at the close of the meeting at St. Paul, asked me whether he should operate in a case of caries of the tibia in a poor woman at a station where the only physician was a homœopath. "Do it if you dare. You shall never cross our threshold if you do. Let her die first."

[This paper caused very considerable comment among the members of the Association, and when it became known that Dr. Gihon had been nominated as one of the Vice-presidents of the Association by the Committee on Nominations, active steps were at once taken to reject the nomination.

The Committee on Nominations, of which Dr. Gihon was a member, was reconvened and his nomination reconsidered. Dr. Gihon then offered a formal written statement to the Committee that he was in favor of the Code of Ethics of the American Medical Association; in consideration of which it was resolved that the report of the Committee, as originally adopted, should be presented to the Association, together with the written statement of Dr. Gihon.]

WEDNESDAY, JUNE 6TH, SECOND DAY.

DR. H. A. JOHNSON, of Ill., presented a statement of the work done by the

ILLINOIS STATE BOARD OF HEALTH.

This paper set forth what the Board has accomplished since its organization, in 1877, for the profession. It is the purpose of this Board to root out all incompetent men practising medicine in that State. At the date of the foundation of the Board, the profession embraced 7,400 individuals, and was composed of 3,600 graduates in medicine, and 3,800 non-graduates, itinerants, and nondescripts, who combined various other vocations with that of doctor. These, almost without exception, belonged to some of the irregular schools. A very small portion of this number now remains, through the efforts of the Board, and the existence of those that remain is due to what is known as the ten years' prior practice clause of the medical practice act.

THURSDAY, JUNE 7TH, THIRD DAY.

The following resolutions concerning

MEDICAL EDUCATION,

offered by DR. GIHON, in connection with his paper on the first day, were taken up and discussed.

Resolved, That the Section in State Medicine urges upon the Association the necessity for at once taking steps to exclude unqualified members from the profession by refusing fellowship to illiterate, ignorant, and incompetent graduates.

Resolved, That the Association be recommended to authorize the Section in State Medicine to act as a standing committee on medical education, the several elected members being required to communicate without delay (I) with the several State medical societies, and the Legislatures of the States they respectively represent, with the object of creating State Boards of Medical Examiners, where such are not already in existence, whose certificate shall be necessary to the issue of a license to practise medicine in that State; and (II) with the authorities of every regularly organized medical college in that State, which has not already taken such action, urging upon them, first, the requirement of a proper preliminary education of matriculants, to embrace at least a knowledge of English orthography and grammar, the etymology of the more common Greek and Latin derivations, and the fundamental rules of arithmetic, to be ascertained by a written examination preserved for reference; and second, greater care in ascertaining the fitness of candidates for a degree, by making their final examination in part a written one, to be kept on record, and accessible for inspection by State Boards of Medical Examiners, Board of Censors of medical societies, or other authorized persons requiring information as to the professional qualifications of graduates.

Resolved, That, in the opinion of the American Medical Association, medical colleges should confer upon graduates the degree of Bachelor in Medicine, such graduates to be eligible to the degree of Doctor in Medicine at the end of three years, after having given satisfactory evidence of their qualification to the Board of Censors of the State Medical Society.

Resolved, That Article II. of the plan of organization of the American Medical Association be amended by this additional proviso:

Provided, That every permanent organized State, county, or district medical society entitled to representation in this Association shall be required to appoint a Board of Censors, who shall rigidly scrutinize the literary and professional qualifications of every candidate for membership therein, and hereafter no delegate shall be admitted to a seat in this Association who shall not have received the certificate of such a Board of Censors or of a State or National Board of Medical Examiners.

The first two resolutions were voted down, and Dr. Gihon then withdrew the remainder.

MEDICAL SERVICE ON OCEAN STEAMSHIPS.

DR. A. N. BELL, of New York, called attention to the condition of emigrant ships, and introduced a resolution as follows:

"Being impressed with the truthfulness and importance of the Memorial of the Parliamentary Bills Committee of the British Medical Association, under date of March 17, 1883, the American Medical Association urges upon the Congress of the United States the subject of competent medical and sanitary service and proper provision for its maintenance on board all transoceanic passenger vessels, and that a committee of five be appointed to promote this object and to report upon the condition of the subject at the next session." The resolution was adopted.

SECTION OF OPHTHALMOLOGY, OTOLOGY, AND LARYNGOLOGY.

WEDNESDAY, JUNE 6TH, SECOND DAY.

DR. L. TURNBULL, of Philadelphia, read a paper on

TINNITUS AURIUM AND THE DEAFNESS WHICH ACCOMPANIES DIFFERENT FORMS OF BRIGHT'S DISEASE,

in which he reported several cases, and presented the following conclusions: The symptoms of disturbances of hearing may be an assistance in the diagnosis of the early and obscure stages of Bright's disease. At times, all other symptoms being absent, only cardiac hypertrophy with auditory symptoms are noticed in interstitial nephritis, and the diagnosis may be confirmed by examination of the urine.

DR. FROTHINGHAM, of Mich., asked whether there were any pathognomonic symptoms. He thought that the eye and ear symptoms might be due to that disease of the arterioles which later attacked the kidneys.

DR. CONNOR, of Detroit, said that these aural symptoms would be a very valuable addition to our knowledge, if they were pathognomonic; but he had seen similar symptoms which had no connection with any systemic disease.

DR. TURNBULL, in concluding the discussion, said that he had not noticed any ataxic symptoms in his cases; the subject was too new for him to state whether the symptoms of serous effusion and injection of the tympanic membrane, which he had noticed in all his cases, were pathognomonic or not.

DR. J. L. THOMPSON, of Indiana, then read a paper entitled

QUESTIONS ON THE ETIOLOGY OF SOME FORMS OF LENTICULAR OPACITY,

in which he described a peculiar opacity of the lens, occurring chiefly in the lower periphery, which comes on suddenly, and remains unaltered for years.

DR. NOYES, of New York, said that he had seen similar cases quite frequently, and he divided them into two classes: Those accompanying myopia and being of a molecular form; and those in which the opacity is striated and is caused by choroidal retinitis. He thought the opacity was due to impaired nutrition of the hexagonal epithelium, and that it required years for its development.

DR. HOWE, of Buffalo, said that each such contribution to our knowledge of cataract only showed how much remained to be discovered in regard to its etiology. He mentioned a case of soft cataract in which the lenses were apparently exactly in the same condition, and yet under a similar operation the behavior of the two was entirely different. Reference was also made to experiments upon rabbits: in these animals there being a decided tendency to repair after injury to the capsule. With them, considerable opacities of the lens will sometimes clear up, so as to leave only a slight cicatrix.

DR. H. CULBERTSON, of Ohio, read a paper on *A Case Illustrating the Segmental Feature of Glaucoma.*

DR. J. O. ROE, of New York, then read a paper on

NASAL DISEASE, A FREQUENT CAUSE OF ASTHMA,

in which he stated that irritation and obstruction of the nasal chambers would give rise to asthma; and that the asthma of hay-fever was chiefly due to the nasal irritation.

DR. SEILER, of Philadelphia, said that he fully agreed with the author, and that in one case under his observation an attack of asthma had been produced by touching a tender spot in the nose with the end of a probe, and that all the asthmatic symptoms disappeared after the spot had been cauterized. He was also of the opinion that hay-fever is due to nasal catarrh of a hypertrophic variety, and that the mucous membrane becoming irritated by the pollen germs gives rise to the well-known symptoms. He had cured cases of hay-fever by removing the hypertrophic catarrh.

DR. FROTHINGHAM said that he could not see how inflammation of the nasal cavity could exist for any length of time without a tendency to extend into the mucous membrane of the bronchial tubes, and that then these cases would not be different from ordinary cases of the disease.

DR. ROE, in closing the discussion, said he was very glad that Dr. Seiler had supported him in his opinion, and that it was not necessary to have bronchitis in all cases of asthma, but that the congestion of the mucous membrane of the bronchial tubes might readily be produced, which in the beginning produced the asthma.

THURSDAY, JUNE 7TH, THIRD DAY.

DR. J. F. RUMBOLD, of Missouri, read a paper on the *Appearance of the Diseased Mucous Membrane of the Nose and Throat of Adult Patients.*

DR. J. J. CHISOLM, of Maryland, then read a paper entitled

IS ABSCISSION A PROPER OPERATION?

He said that the irritation of an artificial eye over a stump is greater than when a shell is carried in an eyeless socket, because in the latter case the surface of contact is reduced to a minimum. If, however, movement of the shell is as good after enucleation as after abscission, the latter operation has no advantage.

DR. FROTHINGHAM said that abscission should be abandoned. The uninjured eye should be the objective point, and no risk of sympathetic inflammation from the shell should be incurred for the sake of cosmetic considerations; further, that the abscission is a more difficult operation than is enucleation, and therefore the risk is greater. The stump is always a source of danger even after a lapse of years.

DR. C. J. LUNDY, of Detroit, had seen cases of total blindness from sympathetic ophthalmia after abscis-

sion. He thinks that the wearing of an artificial eye over these stumps often produces great irritation; that he had seen a case of ossification of the ciliary body and choroid as the result of irritation from the wearing of an artificial eye over such a stump.

DR. THOMPSON, of Indianapolis, coincided most fully with the views expressed by Dr. Chisolm, and mentioned several cases of panophthalmitis following abscission; and two cases occurred under his own observation where two formerly healthy eyes were sacrificed and vision totally lost after the operation of abscission.

DR. CULBERTSON, of Ohio, said that he had never had an unfavorable result in abscission, and he thought his success was due to the fact that he did not put any stitches in the eyeball.

DR. CONNOR said he had seen disastrous results following the operation of abscission.

DR. NOYES said he had formerly performed the operation often, but had never seen bad results follow. In all these cases he had, however, advised enucleation of the eye. He thought that suppuration prevented sympathetic inflammation in the other eye, and in the case of a foreign body, he should always advise enucleation; and he thought that the safety of the uninjured eye was the main point.

DR. CHISOLM, in closing the discussion, said that formerly he had been in favor of abscission, but that now he considered an injured eyeball, whether from operation or from accident, a source of great danger.

SECTION ON DISEASES OF CHILDREN.

WEDNESDAY, JUNE 6TH, SECOND DAY.

DR. A. Y. P. GARNETT, of Washington, D. C., read a paper upon

EPIDEMIC JAUNDICE AMONG CHILDREN.

In his experience, he said, epidemic jaundice had been confined to children. He related the history of an epidemic which had come under his notice during the months of July and August, 1881. He had under observation six cases, of ages varying from two to six years. The cases occurred at that season of the year when the temperature attained its maximum elevation, and none were in parts of the city supposed to be exposed to malarial influences.

DR. BLAINE, of Pa., spoke of cases which had come under his observation, in which he had attributed the disease to heat.

DR. W. SHEEHAN, of New York, spoke of a case which had come under his observation on a warm, spring-like day in the month of February, the child not being properly protected against the weather. He expressed the opinion that in some cases cold was also an important factor.

DR. WM. LEE, of Baltimore, spoke of nervous influences as an exciting cause, and referred to a case which had come under his observation in midwinter.

DR. ALEXANDER HARRIS, of Virginia, then read a paper on

THE UNITY OF DIPHTHERIA AND MEMBRANOUS CROUP.

He claimed the identity of the diseases and thought that it was only necessary to prove the identity of laryngeal with pharyngeal false membrane to establish his point.

DR. SNOW declared his belief in the individuality of the two diseases. He said that one is a contagious disease, the other is not; one usually has its starting-point in the pharynx, the other in the air-passages.

THURSDAY, JUNE 7TH, THIRD DAY.

DR. GOOD, of Indiana, read a paper on

DENTITION.

He said that dentition was not classed as a disease, but the diseases which accompany it are numerous. He advocated lancing the gums when swollen, or when there is functional derangement of the stomach and bowels.

DR. EARLE, of Illinois, said that in teething infants he had checked severe diarrhœa, amounting almost to cholera infantum, by simply lancing the gums and without any medication, only paying attention to diet.

DR. GOODWIN ORTH, of Indiana, said that in his experience of thirty-three years, he had been in the habit of lancing the gums, and frequently found that it gave instantaneous relief, and he believed that the teeth came out more readily with scarification than without.

DR. J. B. CASEBEER, of Auburn, Ind., then read a paper on

PEDIATRIC MEDICINE AND ITS RELATION TO GENERAL MEDICINE.

He urged that diseases of children speak as plain a language, and require as direct remedies to control them as do those of the adult.

DR. NORMAN TEALE, of Indiana, read a paper on *Infantile Paralysis*, and detailed the history of a typical case.

THE EXHIBITION HALL.

The exhibition of pharmaceutical preparations, surgical instruments, and medical publications was held in the Tabernacle, a large but by no means handsome building situated about three blocks from Case Hall, in which the general sessions were held. The attendance of physicians was far from being large, in spite of the very handsome appearance made by several of the exhibitors and the attraction of a practically unlimited number of samples of all kinds.

Messrs. Park, Davis & Co. had a large space, and showed many of the new drugs of which they make a specialty, both in the crude and manufactured state.

McKesson & Robbins, of New York, had one of the handsomest exhibits in the Hall, and displayed among other preparations seventy-six different alkaloidal salts of the cinchona bark.

W. R. Warner & Co., of Philadelphia, had an attractive stand, and devoted especial attention to their new parvules for medication in small, often repeated doses.

C. H. Phillips, of New York, offered sterling attractions, in the estimation of visitors, by dispensing cups of a new preparation of phosphated cocoa.

Among other manufacturing pharmacists represented were Wyeth & Bro., Schieffelin & Co., E. G. Houghton & Co., Metcalf & Co., Mallinckrodt & Co., and Powers & Weightman, the last two firms exhibiting fine chemicals only.

One of the neatest exhibits was made by Lambert & Co., of St. Louis, whose ebony stand and rich Turkish rugs attracted considerable attention.

Among the surgical instrument-makers, John C. Frye, of Portland, Me., and John Reynders & Co., of New York, were the most prominent. Both of these firms had fine exhibits.

The publishers of medical books and journals were somewhat hardly treated, being relegated to an out-of-the-way corner. Messrs. Henry C. Lea's Son & Co., D. Appleton & Co., J. H. Chambers & Co., P. W. Garfield, and D. G. Brinton were all represented.

The general feeling among exhibitors seemed to be that a more centrally located hall might have been procured; but in other respects the Committee having charge of the exhibits acquitted itself admirably.

AMERICAN SURGICAL ASSOCIATION.

Fourth Annual Session, held in Cincinnati, May 31, and June 1 and 2, 1883.

(Specially reported for THE MEDICAL NEWS.)

(*Concluded from p. 672.*)

AFTERNOON SESSION.

DR. J. M. BARTON, of Philadelphia, presented a

SPLINT FOR EXTENSION OF THE WRIST-JOINT

which he had used for some years, in synovitis of the wrist-joint. The splint was a light one, yet is capable of making powerful extension, is not conspicuous, and permits some use of the fingers. It was made of wire, is eleven to thirteen inches long, and from one and a half to two inches wide. It is placed on the palmar aspect of the forearm, reaching from a little below the bend of the elbow to below the lower end of the metacarpal bones. The extension is made by a piece of heavy rubber elastic, which is fastened to a cross-wire at the upper end, and passes over a roller at the other end of the splint. The speaker then entered at some length into the consideration of the advantages of his invention, and explained fully its conveniences by making a practical application of it.

DR. DAVID PRINCE, of Jacksonville, Illinois, presented his

RECTAL OBTURATOR,

which consists of a hollow rubber ring, capable of being expanded by air or water, and provided with a central aperture through which a tube or hollow bougie may be passed for conveying water into the intestine. In using the obturator, it is pushed into the rectum, through the sphincter, then distended, and the bowel filled through the bougie. Its applicability is obvious for all cases in which a large quantity of fluid is to be introduced into the rectum, whether the fluid be water, for the relief of constipation, obstipation, strangulation, or simply to reduce the temperature by thinning the blood; nutritious fluids, or alcohol for stimulation or anæsthesia.

DR. PRUITT stated that he believed that an ordinary syringe would answer every purpose of the obturator, and cautioned against the danger of over-distention and consequent rupture of the bowel. Then again, said he, it is in some cases exceedingly difficult to make a differential diagnosis in cases of obstruction of the bowel; and while the injection of large quantities of water or of air in cases of simple obstruction might do very well, in cases of volvulus it would lead to a rapidly fatal result.

DR. CAMPBELL expressed his unbelief in the value of nutritious enemata. How, he said, can nutritious substances be digested in the rectum? They must enter the small intestine.

DR. PRINCE replied to these objections by stating that, in the first place, it was not intended that great force should be used in injecting the fluid or air, but only that a large quantity might be introduced, the obturator enabling the patient to overcome the involuntary efforts at evacuation which followed the first introduction of fluid. Used in this way, he could not only force water up to the point of obstruction, but could estimate, from the quantity required to reach that point, the location of the difficulty. As for Dr. Campbell's objection, he considered that an argument in favor of his instrument, for the great reason for the failure of nutritive injections, he thought, was that too small a quantity was always employed, and the fluid did not pass far enough into the bowel.

Next in order was a voluntary paper on

STRICTURES OF THE ŒSOPHAGUS,

with cases and the treatment, by HENRY F. CAMPBELL, M.D., of Augusta, Ga. The frequency of injuries to the œsophagus, resulting in obstruction and disability of the tube for the transmission of food to the stomach, he said, gives them an importance well worthy of the careful consideration of the surgeon. The object of the present paper was, however, mainly to express the experience of the author in a number of cases which it had fallen to his lot to witness privately or in consultation. The muscular layers of the œsophagus make it very liable to spasmodic contraction upon any irritation of its mucous membrane. The comparison which most authors make of the œsophagus and urethra is most fallacious. The recently recommended division of strictures of this tube is a highly objectionable procedure, and is in every way inferior to the safer although slower process of dilatation; and he had as yet found no case that was not amenable to this treatment. He then entered briefly into a discussion of the causes of the complaint, and narrated four cases which had come under his own treatment. In all of them, the stricture had been remarkably close and firm, but by the frequent and long-continued passage of sounds, he had succeeded in effecting a cure. He considered the ordinary flexible olive-pointed urethral bougie the best form of instrument for the early treatment, gradually increasing the size until a large œsophageal sound can be passed.

DR. PRINCE reported the case of a child two years and a half old, that had swallowed lye, and in which he had gotten relief by the passage of an electrode, using the constant galvanic current. The third attempt succeeded in reaching the stomach. In a week solid food could be eaten.

Owing to the lateness of the hour, DR. C. H. MASTIN, of Mobile, Ala., was compelled to give only a very brief sketch of the points he had intended bringing out in his paper, entitled

SOME REFLECTION UPON THE OPERATION OF EXTERNAL PERINEAL URETHROTOMY.

He stated a few of the better methods and described briefly the method he employed in certain cases. He closed by cautioning against the use of persulphate of iron in hemorrhage from such operations.

DR. CAMPBELL, of Augusta, Ga., now presented

A NEW SPLINT

devised by Dr. John S. Coleman, of Augusta. The instrument consisted of two felt splints for the forearm, secured by leather bands with straps and buckles, one below and one above the elbow. A brace connected with these bands prevented all motion. The splint was obviously intended for the treatment of fractures in or about the elbow.

THE PRESIDENT now called an

EXECUTIVE SESSION,

in which the following business was acted upon:

A motion to increase the membership from one hundred to one hundred and fifty was lost.

VOLUME OF TRANSACTIONS.

The Recorder was authorized to publish in a handsome and substantial volume, the full report of the Transactions of the Association during the four years of its existence.

The following

NEW MEMBERS

were elected: H. K. Steele, M.D., of Denver, Col.; Herbert Judd, M.D., of Illinois; Thomas M. Markoe, M.D., of New York.

THE LIBRARY AND MUSEUM OF THE SURGEON-GENERAL'S OFFICE.

A resolution was adopted petitioning Congress for an appropriation of sufficient money to complete the publication of the indexed catalogue of medical books in the National Medical Library, and to provide for the Museum and Library, a fire-proof building.

THE CODE OF ETHICS.

The following resolution was offered by the Council, to whom the subject had been previously referred, and was adopted by the Association:

Resolved, That the Secretary be instructed to address a communication to each Fellow, active or honorary, who is alleged to have violated the Code of Ethics adopted by the American Surgical Association, and request him to withdraw if the allegations be true.

THANKS TO THE RETIRING PRESIDENT.

The Secretary then read the following resolution offered by DR. W. W. DAWSON:

Resolved, That a vote of thanks be returned to our retiring President, Samuel D. Gross, and that the members of the Association unite in the hope that he may be long spared to meet with us, to cheer us by his presence, and to guide us by his wise counsel.

AN ANNUAL BANQUET.

It was also resolved that hereafter a banquet should be given at the expense of the Association, the local committees of arrangements to make all necessary provisions for the same.

PRESIDENT GROSS then made the following

VALEDICTORY.

Let me congratulate you, gentlemen, upon the success of this, the Fourth Annual Meeting of the American Surgical Association. I have been your presiding officer from the inception down to the present moment. I feel honored, and highly appreciate what you have done for me. In all your deliberations I have endeavored to act with an eye single to the interests of the Association, and with that impartiality which has always characterized my actions in all my relations to the Association.

Now that I am about to retire from the discharge of these duties, I am assured that the interests of the Association will be perfectly safe in your hands and the hands of my successors. I have no greater ambition, gentlemen, than to live in your affection and your esteem, and to witness the ever-increasing success of the Association. Its success is closely associated with the remainder of my life, for I believe that we have established an Association that will yet exert a great power for good in the land; and when I die, as I must, I hope you will bear in mind that I trust to your keeping the good of the American Surgical Association.

God bless you, gentlemen; and may you wend your way home to receive that welcome which I know will be extended to you. May God bless you in all your relations in life, and I hope that you will always be faithful to the interests of your profession, and faithful to the Code in connection with which we have carried on our transactions.

The Association then adjourned, to meet in Washington, D. C., on the Wednesday preceding the annual meeting of the American Medical Association in 1884.

MEDICO-CHIRURGICAL SOCIETY OF MONTREAL.

Stated Meeting, April 27th.

(Specially reported for THE MEDICAL NEWS.)

(*Concluded from page 638.*)

THE PRESIDENT, R. A. KENNEDY, M.D., IN THE CHAIR.

THROMBOSIS AND EMBOLISM OF THE SUPERIOR MESENTERIC ARTERY.

DR. OSLER showed the specimen from the preceeding case, and referred to other instances which he had met with. In Dr. Wood's case, the fatal result was directly due to infarction of the bowels, caused by a thrombus in the superior mesenteric artery, the orifice of which was narrowed by a large button of atheroma. This had ulcerated on the surface, and a thrombus had formed which completely blocked the vessel for an inch and a half. This was the third case he had met with of plugging of this vessel, and as the condition was rare and the effects peculiar, he would refer to them.

In February, 1877, a woman aged about 75, was admitted to hospital under Dr. Ross with necrosis of the femur. She was seized with severe abdominal pain, vomiting frequent, diarrhœa at first, and then symptoms which pointed rather to obstruction, persistent vomiting, and great distention of the belly.

At the autopsy the small intestines were found greatly distended and of a deep livid-red color; no inflammation of the peritoneum but about one and one-half pint of bloody serum in the sac. The coats of the bowel were swollen and infiltrated with blood and serum. For about a foot from the pylorus the appearance of the gut was normal, and the last six or seven inches of the ileum were also healthy. The mucosa was deeply congested, soft, and readily scraped off.. The mesentery was congested and infiltrated. In the *heart*, the mitral valve presented numerous recent warty vegetations, soft, pedunculated, and easily torn. The aorta was moderately atheromatous. Dissection of the cœliac axis showed the splenic artery blocked by firm brownish thrombi, which extended from about an inch from the hilus into the branches of the second and third degree. The organ was small and had a turbid, reddish-brown appearance. The hepatic artery was occluded by a firm thrombus, which began near the bifurcation and extended into both branches. The superior mesenteric artery contained a firm brownish-yellow clot, which began about a quarter of an inch from the aorta and extended an inch and a half into the two main branches. Before this chief division six smaller vessels were given off, all of which were plugged. In tracing down the large branches, two of them contained firm thrombi about an inch from the bowel.

A second case was the following:

J. C., aged 40, an engineer, large, muscular man, patient of Dr. Gardner. Good health up to a year before death, when he began to suffer with pains in the back. While wheeling a barrow full of cinders, was suddenly seized with intense pain in abdomen and groins; became faint; fell to the ground, and vomited. He lived for a week after. The chief symptoms were persistent vomiting, which resisted all the usual remedies; severe diarrhœa; great pain in abdomen, which was distended. The voice was husky; eyes sunken; features pinched, and the whole appearance choleraic. The stools were thin, and at times blood-tinged. The temperature did not exceed 101°; pulse was small and infrequent, rarely over 90. The autopsy revealed an abdominal aneurism, involv-

ing the aorta just at the diaphragm. The axis, superior mesenteric, and renals were given off from the sac. There was a beautiful dissecting aneurism of the lower part of the abdominal aorta and the iliac. The blood had passed from the sac beneath the intima at the hinder part of the aorta, and on the right side, and had passed into the iliac, elevating the intima, and narrowing their calibre. On the right side of the external iliac, it had burst externally by a tiny orifice, and a thin sheeting of blood extended beneath the pelvic peritoneum and in the lumbar region. The small intestines were swollen, of a deep purple-red color; the walls infiltrated with blood and serum. They contained a thin, blood-stained fluid. The superior mesenteric artery arose from the most prominent part of the sac, and the orifice was dilated. About half an inch within the vessels was a firm plug of the fibrinous lining of the sac which had been dislodged and carried into the artery. There was a pretty firm coagulum about it, and, on the distal side, a dark clot. The mesenteric veins were full, and the membrane thickened and infiltrated.

Functionally, the mesenteric arteries are *terminal* ones, and, when plugged or tied, hemorrhagic infarction of the bowel takes place, as the collateral circulation cannot be established. Anatomically, the collateral channels do exist, but Litten has shown that the blood-pressure is never high enough in them to fill the long series of branches when the superior mesenteric is occluded. In horses, the occurrence of embolism of the mesenteric vessels is common, as portions of the thrombi from verminous aneurisms get dislodged, and plug the smaller branches. It is the chief cause of colic in these animals.

SARCOMA OF KIDNEY.

DR. ALLOWAY related the case and presented the specimen. A girl, aged 5, was brought to him on December 8th, by her parents, who had noticed a swelling in the abdomen. He found a pear-shaped tumor on the right side in the situation of the kidney, extending to within an inch of the crest of the ilium. She did not complain of pain, and seemed pretty well. On January 22d, was again examined, and the tumor found to have increased in size; a distinct bruit was heard, loudest over the maximum elevation of the growth, and fading towards epigastrum and the spine. The heart was displaced upward, and to the left; sounds normal. The child wasted rapidly, and the tumor continued to grow, until it appeared to fill the abdomen. No pain, no œdema of legs; superficial veins not enlarged; appetite and digestion good, death from exhaustion. The autopsy revealed a large mass occupying the greater part of the abdomen, particularly the right side, to which it was attached. The cæcum and ascending colon were embedded on the left side, and at the upper end, the duodenum was stretched along the margin. It was readily peeled out, and brought with it aorta and cava, which were deeply embedded posteriorly. On the anterior surface, were several large loose hemorrhagic folds, which overlapped the cæcum. The mass was the enormously enlarged, sarcomatous kidney, very soft, vascular, and at the convex border presented a small thin shell of renal substance. The inferior cava and right iliac were compressed, and the latter contained a thrombus. The right iliac artery was also full of grayish sarcomatous masses; microscopically, the mass was composed of small round cells, with but little supporting tissue beyond that which accompanied the bloodvessels. A specimen was shown under the microscope.

SCIRRHUS OF PANCREAS; SECONDARY COLLOID OF LUNGS.

DR. OSLER presented the specimens which had been taken from a woman, aged 52, who died under his care in the General Hospital. She had not had any symptoms pointing to abdominal trouble, but there were shortness of breath, cough, and latterly great lividity. Percussion note was deficient in resonance all over the chest, and dull at right base; numerous whistling and mucous râles. At the autopsy, there was found a small firm cancer of the body of the pancreas, not involving the head or compressing the duct. Both lungs were stuffed with masses of colloid cancer, and presented a remarkable appearance from the number of the translucent, jelly-like tumors. Many of them were isolated, others formed large irregular areas, as the right base. The alveoli of the cancer, distended with the colloid substance, could be plainly seen.

URÆMIC COMA, VERY SLIGHT RENAL CHANGES.

DR. OSLER referred to the case, and showed the specimens, which illustrated the necessity of microscopical examination of the kidneys before pronouncing on their healthy or diseased condition. A man, aged about thirty-six, was found by the police in an unconscious state, and brought to the hospital at noon on the 25th. When seen at 4.30 P. M., he was profoundly comatose, livid, and cold; pupils of moderate size; no sign of injury. The urine was drawn off, found to be highly albuminous, and contained casts—hyaline and epithelial. There was no œdema of ankles. Death about 10 P.M. The brain presented some œdema of the membranes, but the substance was not specially moist; no coarse lesions. The kidneys were undersized, right weighed ninety grammes, left one hundred and twenty. Capsules detached easily; surfaces smooth, not in the least degree granular. On section, not very firm; cortices not reduced; no special congestion; arteries not thickened. Close examination showed pale areas in the cortices, particularly near the pyramids. The organs would certainly have passed a superficial inspection. Microscopically, the tubular changes were found to be considerable; epithelium swollen, granular, and fatty, and many of the collecting-tubes contained casts. The majority of the tufts in the sections appeared normal, but here and there a shrivelled, atrophic one was met with, and about some of them there was an increase of connective tissue.

DR. SHEPHERD exhibited the following specimens:

(1) ABNORMALITIES OF THE AORTIC ARCH.

(a) An example of a large middle thyroid artery, which arose from the innominate. It passed up the middle of the neck, lying on the trachea and divided, half an inch below the cricoid cartilage, into two branches which went to the right and left side of the trachea.

(b) Two examples of the left carotid arising from the innominate artery instead of from the arch. This was mentioned as being the commonest variety of abnormal arch, and as being the normal arrangement in many animals, as the dog, rabbit, cat, etc.

(c) A left vertebral arising from the arch between the left carotid and left subclavian arteries. It was of large size. The right vertebral was very small, not being larger than a crow-quill. The branches from the right subclavian in this case came off separately, no thyroid axis being present.

(2) DOUBLE SUPERIOR VENA CAVA, OR PERSISTENCE OF THE LEFT DUCT OF CUVIER.

This specimen was obtained from a female subject, aged about 65. The persistent vein was the size of a good-sized pen-handle, and the transverse or left innominate vein was not much reduced in size, as is the case when the persistent duct is larger. This was the second example of this anomaly that Dr. Shepherd had

met with, and he stated that the left duct of Cuvier persists normally in birds and some mammals.

(3) A PREPARATION OF AN ABNORMAL RIGHT OBTURATOR ARTERY GIVEN OFF FROM THE EPIGASTRIC.

The obturator passed to the inner side of the femoral ring.

(4) DISSECTION OF A CASE OF TALIPES VARUS (LEFT).

Dr. Shepherd obtained this specimen from a subject in the dissecting-room, aged about 45. The foot had never been operated on, and was a pure case of talipes varus. The deformity was due, principally to the contraction of the tibialis anticus, extensor proprius hallucis, and extensor communis digitorum muscles. Operation by division of the tendons would have relieved the deformity.

PUERPERAL CONVULSIONS.

DR. ARMSTRONG read a paper on three cases which had been under his care.

Case I.—Mrs. P., aged 30, second pregnancy, delivered February 4, 1881. A fortnight before delivery she complained of headache, dimness of vision, and pain in the abdomen. The feet, hands, and eyelids were swollen, and the urine was highly albuminous. She lived out of town, and was not seen again until the morning of her confinement. Found os dilating and parts normal; the œdema had almost disappeared. Fearing convulsions during an absence of a few hours, she was ordered ℈j of chloral every hour. On returning, found that she had had a severe convulsion. Os was now fully dilated, but while making the examination a convulsion came on; chloroform was at once administered, the membranes ruptured, and the child delivered with the forceps. Considerable hemorrhage followed. The child was still-born.

Case II.—Miss M., aged 29; when first seen, February 10th, had been in labor twelve hours. Os dilated, membranes ruptured, and head well down on perineum. Pains were strong, and recurred every two or three minutes. She complained of inability to move the right arm, and there appeared to be some degree of feebleness in it. No œdema effect. In a couple of hours the child was born. Just after the removal of the placenta, she was seized with a severe convulsion; chloroform was given and liq. opii sed. ♏xxx injected hypodermically. After the convulsion had passed away the patient remained unconscious, and remained so through the day; no paralysis; pupils equal. In the evening she had three mild convulsions; one-fourth of a grain of pilocarpine was injected, the loins dry-cupped, and ℥j of chloral given per rectum. Urine drawn off and found highly albuminous. Pulse 70, temperature normal. February 11th, no return of consciousness; will not swallow liquids. Pulse 110, temperature 101°. In the evening, coma had deepened. 12th. Pulse 132, temperature 102.5°; fourteen convulsions through the night; gave one-fourth of a grain of digitaline (Parke, Davis & Co.) and the pulse fell to 116. Leeched the temples; coma deep; pupils contracted. At 2 P.M., one-half grain of pilcocarpine, and the digitaline repeated. Slight facial paralysis on right side. She grew rapidly worse, temperature rose to 104°, had two more convulsions at 8 P.M., and died shortly after midnight. At the autopsy, the vessels of pia mater distended; frontal lobes covered with extravasated blood, which extended on and appeared to come from the parietal lobe of the left side. On section of the organ (Pitres' method) prefrontal and pediculo-frontal sections normal. The frontal contained on the left side, the anterior wall of a cavity which held a large clot, which reached the cortex. The parietal section cut the centre of the clot, which measured four by four centimetres; no blood in ventricles. The kidneys were enlarged and pale, capsules adherent, epithelium in state of granular swelling, veins much engorged. In this case it is possible that the hemorrhage may have taken place or have begun before the convulsions set in, as she complained of numbness in the right shoulder, and loss of power in the right arm.

Case III.—Mrs. S., aged 35; second pregnancy. Sent for on Sept. 15, 1882. Patient had had a convulsion two hours before my arrival, and during the visit, a second. No sign of labor; fœtal heart-sounds distinct. She complained of headache, and was vomiting. Urine highly albuminous. Ordered chloral, ℥j, per rectum, to be repeated whenever patient complained of any special head symptoms or twitchings. Three weeks elapsed without any further trouble, during which time she had sometimes two or three doses of chloral in the day, and again, two or three days would pass without any. Diuretics were given continuously, and occasionally a purge. The urine remained very albuminous. Patient was delivered of a healthy, living child, and made a good recovery. This case bears on the question of the induction of labor on the appearance of convulsions. The patient went twenty-two days after two severe attacks, and then did well.

DR. WILKINS exhibited sections of the kidney of the second case, which showed granular degeneration and swelling of the renal epithelium, and unusual distention of the small veins. In sections of the medulla, the veins were also greatly distended, and in one portion there appeared to be minute capillary extravasation. With regard to the induction of labor, in a case which he had last August, when the convulsions began labor had set in, and the fœtal heart-sounds were strong. The attacks followed every hour, and the heart-sounds of the child become weaker. He then delivered with forceps. The child had convulsive paroxysms for twenty-four hours. In this instance, he believed that if the delivery had been longer delayed, the child would have been dead.

DR. ALLOWAY referred to the various views current regarding the etiology of eclampsia, and to the possible effect upon the child of the uræmic condition. In the treatment, he had been using lately large doses of morphia—two or three grains hypodermically—as recommended by Clarke, of Oswego.

DR. RODGER had had very many cases, and had tried all the forms of treatment. In the last two he had used morphia in large doses, but as venesection was also employed, he was in doubt as to which to attribute the good results. Chloral and chloroform had proved useless in his hands. In the uræmic convulsions of ordinary Bright's disease, he used pilocarpine, but had not been impressed with its benefits in the puerperal condition.

DR. TRENHOLME remarked that the mental state of the patient was a factor in the causation; thus, the anxiety and grief of unmarried women at this period was, he felt sure, a predisposing cause. When the contraction of the uterus appears to usher in the convulsion, his practice is to hasten labor. The treatment varies with the case. When the patient was plethoric, he bled freely; but he had usually found chloroform, supplemented by chloral and bromides, controlled the convulsions. The death of the child he attributed to separation of the placenta from the uterus, thus cutting off the circulation, and inducing suffocation.

DR. RODDICK stated that, some years ago, when engaged in midwifery practice, he had found chloral of the greatest value in a number of cases. What he wished to call the attention of the Society to, was that, some years ago (1876), their colleague, Dr. Fuller, who had since removed to Grand Rapids, Mich., had read

a paper on convulsions, in which he advocated the treatment by morphia, in full doses. He remembered well that, at the meeting, Dr. Fuller was almost alone in his views; he would now find many supporters.

DR. PROUDFOOT suggested that large doses of chloral might in some cases account for the death of the child.

DR. CAMERON thought that the convulsions were not always due to kidney complications and uræmia. He had recently had a case of an epileptic woman, who had a severe convulsion shortly after delivery. He had treated two cases satisfactorily with morphia. The want of success with chloral he attributed largely to the fact that it was not absorbed.

DR. WOOD relied chiefly on venesection. In one case, recently, in which convulsion came on after delivery, he had bled to fourteen ounces, with good effect; but the patient now had persistent anæmia.

DR. OSLER remarked, on the occurrence of cerebral hemorrhage in puerperal convulsions, two cases which had been met with in the University Lying-in Hospital during the past few years, and he had shown, at the last meeting, a specimen of ventricular hemorrhage from one of them.

DR. KENNEDY believed that in all cases in which uterine contractions were present, and were possibly the exciting cause of the convulsions, labor should be hastened. He used chloroform, and gave chloral and bromides. Venesection was of most value before delivery. He was in the habit, in cases of convulsions, of not exercising any pressure on the uterus, but rather favored slight flow of blood.

DR. CAMPBELL was glad to hear the general expression of opinion in favor of venesection, a practice in which he had the fullest confidence.

DR. ARMSTRONG then briefly replied.

MASSACHUSETTS MEDICAL SOCIETY.

One Hundred and Second Annual Meeting, held at Boston, June 12 and 13, 1883.

(*By Telegraph.*)

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, JUNE 12TH, FIRST DAY.

MORNING SESSION.

THE Annual Meeting of the Massachusetts Medical Society was called to order in Huntington Hall, at the Institute of Technology, Boston, at noon, by the VICE-PRESIDENT, DR. JOHN H. MACKIE, of New Bedford, who announced that the first paper to be read was,

A CONTRIBUTION TO THE STUDY OF THE TUBERCLE BACILLUS,

by H. C. Ernst, M.D., of Jamaica Plain. The author first referred to the announcement last year of Koch's discovery of the bacillus tuberculosis, which he claimed to be the cause of tubercle. The question of the inoculability of tubercle has attracted increased attention since the promulgation of the views of Koch. His assertions on the subject have been carefully fortified by numerous cultivations and inoculations, and but very few of the many observers who have examined tubercular tissue for the bacillus have ventured to deny its existence. The author then gave a general review of the subject.

Fräntzel, he said, has observed three hundred and eighty cases of phthisis, and has examined eighty other cases of lung diseases, and always with negative results. In every case of phthisis he has found bacilli; in five cases of phthisis no *tubercle* bacilli were found; in other cases, where bacilli were found, none of them were cases of cheesy infectious phthisis. He concludes that the presence of bacilli determines the presence of tuberculosis.

At a meeting of the Vienna Society, Spina read a paper on the subject of Koch's bacillus. He bases his rejection of Koch's theory upon the fact that the bacilli were found to act differently toward fluids from what was supposed. He gives the results of observations as follows: Micrococci of many kinds were stained blue on a brown ground. *A.* In bronchitis sputum. *B.* In sputum of bronchial asthma. *C.* In sputum of diffuse bronchitis. *D.* In the furred tongue of non-phthisical patients. *E.* In the lochia of non-phthisical lying-in-women. *F.* In the sputum of cases of pneumonia. *G.* In the stools of typhus-fever patient. *H.* In the expressed fluid of a case dead of malignant œdema, etc. Stricker addressed the Society in support of Spina and his methods, and Klebs gave the following summary:

1st. That the tuberculosis process is caused by organisms. 2d. That the micrococci are present in the albumen cultures as well as in youngest form of inoculated tubercle. 3d. That the development of the tubercular process begins soon after inoculation. Completely formed tubercles appear only after a longer period, but before their appearance there is extensive cellular deposit; the same primary method of distribution is found in human tuberculosis, in which all the traces of these retrogressive formations in the mesentery and omentum are found in cases of pulmonary tuberculosis. In other cases cheesy foci form in the organs. All the work upon this subject has been for the purpose of identifying the bacillus and determining the frequency of occurrence in tuberculous lesions. The lungs, liver, spleen, kidney, peritoneum, bronchial, mesenteric, and inguinal glands, pia mater, and conjunctiva of the eye have been examined and bacilli have been found. They are less numerous in old or slow processes. The result of my observations is that their presence is diagnostic of tubercle. Bacilli have been found in the bloodvessels and in the lymph-channels. I have never seen anything but a bacillus staining red on a blue ground. The method of staining which I have employed is Ehrlich's.

Record of the examinations of different organs for the detection of bacilli.—A guinea-pig inoculated in the groin with a few drops of tuberculous sputum in December, 1882, died in the middle of January, 1883. Bacilli found in liver, spleen, and peritoneum. 2. A guinea-pig inoculated in the same manner as the preceding, died January 13, 1883. No change in any organ but the liver. 3. A guinea-pig inoculated as the preceding in December 28, 1882, died in March, 1883. The lungs presented no abnormal appearance; bacilli in spleen. 4. A guinea-pig inoculated on March 13th with tuberculous sputum in inguinal region, died in ten days. No bacilli except in spleen; cellular tissue at point of inoculation stuffed with bacilli. 5. A Guinea-pig inoculated in the same manner as first three in December, 1882, died, after emaciation, on April 2, 1883. All organs showed tubercular infiltration, and bacilli were found in lungs, liver, spleen, kidneys, inguinal glands, and skin under the point of inoculation. 6. A guinea-pig inoculated in the eye. The lungs, liver, and glands showed signs of disease, and bacilli were found in giant cells and alveolar walls of portion of lungs, and in the liver. 7. A child of three and a half years, dead of acute miliary tuberculosis. Lungs, liver, and mesenteric gland showed bacilli very distinctly; none in the liver and peritoneum. 8. A cheesy bronchial gland, removed three months before examination and preserved in absolute alcohol. Bacilli were found in plenty in cheesy portions near the edges, and in comparatively healthy tissues beyond. 9. A case of acute miliary tuberculosis in a child;

bacilli in kidney in small numbers in region of straight tubules; also in omentum. 10. A specimen named "gland from autopsy." No evidence of bacilli; the specimen was very old, however. 11. Tuberculosis of lungs; a specimen of very old fibroid phthisis which was almost cicatrized, and no bacilli were made out. 12. Tuberculosis of peritoneum; bacilli were seen in small numbers in tissues in neighborhood of the tuberculous process. 13. This was a specimen sent in as a cheesy mesenteric gland from a case in which death was caused by a perforation of the intestines and subsequent peritonitis; bacilli were not found. 14. Contents of a cheesy cavity from the lung of a rapidly fatal case of tuberculosis, bacilli were found in increased numbers, in some cases cells being stuffed with them. 15. Scrapings from the walls of a lung cavity in an ordinary case of phthisis. Bacilli in immense numbers in some places the whole field filled with them. 16. Contents of a lung cavity in a case of slow tuberculosis. Bacilli in immense numbers. 17. Cheesy cervical gland. Bacilli on the edges in clumps and singly in the giant cells. 18. Case of tubercular meningitis dead after a month's illness, enlarged bronchial gland found and the pia mater full of minute granulations. Bacilli near the edges of the tubercular portion of the glands; pia mater showed fixed bacilli. 19. Tuberculous lung. Bacilli found in the edges of cheesy mass of tubercle, and in the centre, bacilli in apparently healthy tissue. 20. Tuberculosis of lung; this like the preceding was a mass of tubercle with cheesy fascia and cicatricial tissue. Bacilli in very large numbers, near the edges in recent degeneration and less in old fibrous portions. 21. Tuberculosis of a small cavity in cortex of the kidney. 22. Tuberculosis of eye, specimen removed last, and preserved in chromic acid; after standing forty-eight hours. A few bacilli were found in the nodule. 23. Miliary tubercle in a child. Bacilli in large numbers in cells in the tuberculous portions of the spleen.

In the mesenteric glands and in tuberculous ulceration of the intestines, it will be seen that in every case of inoculation tuberculosis was developed, and the microscope revealed bacilli in some portions of the organs of animals used in experiments. The series of sputum preparations is to be commended for its accuracy.

In a series of examinations of phthisical patients, the results were as follows:

1. Thirteen examinations of sputum, with positive results in eleven cases; bacilli varying from none at all to very numerous. 2. Sick for one year; hæmoptysis the first symptom; fourteen examinations with positive results in thirteen; bacilli found in large numbers. 3. Cough for six month; discharged relieved; eleven examinations with positive results in six; bacilli found in five successive examinations. 4. Cough for eight months; from February 17th to April 20th, ten examinations with positive results in nine; bacilli varied greatly in number. 5. Sick for seven years; February 10th to June 3d, fifteen examinations, positive results in nine; bacilli in very small numbers. 6. Sick for three years; hæmoptysis the first sign; from February 17th to June 6th, fifteen examinations with positive results in twelve; bacilli very few until examination, when number had increased greatly, but with no increase in the temperature. 7. Sick one year; hæmoptysis the first symptom; from April 20th to June 3d, four examinations, bacilli in every case. 8. Cough for one year; from May 10th to June 3d, three examinations; bacilli in increasing numbers. 9. Cough for two years; May 19th to June 3d, three examinations; many bacilli in every case. 10 Cough and hæmoptysis for ten years; February 17th to June 3d, fifteen examinations; positive results in six only; bacilli seen in very small numbers. 11. Case of pleurisy; March 14th to May 19th, seven examinations were made, with negative results in every case.

A comparison of the charts show that there is only a very general correspondence between the numbers of the bacilli and the variation of the fever-line.

Continued examinations of the sputum are necessary before the absence of the bacilli can be definitely secured. In rapid cases with free expectoration, there were enormous numbers of the bacilli to be found.

The results of this investigation may be summed up as follows:

A staff-shaped micro-organism exists in all forms of the tubercular process.

Second, it is more abundant in the rapid than in the slow forms of the process.

Third, its specific nature as the cause of the tuberculosis is claimed by Koch on the ground of his observations.

Fourth, the specific character has not been successfully refuted by trustworthy observations.

Fifth, its value as diagnostic evidence is very great, although its absence cannot be considered as excluding that process.

The only observer who has thus far attempted the repetition of Koch's culture experiments is Prof. Feltz, of Nancy, who has announced the failure of his mode. More than one failure must occur to refute the testimony of complete and repeated successes.

At the close of the reading of the paper, DR. R. H. FITZ, of Boston, said that he thought the evidence of Koch demonstrated the existence of bacilli in the tuberculous tissue of the lungs. He thinks the matter in the fluids is the result of putrefaction.

DR. BOWDITCH then stated that he would like to ask Dr. Ernst a few questions. Where did these bacilli come from, since they were found in many forms of disease? Was it proper to wear respirators? Were they in the air? If there is danger from inhalation, should this appliance be used, or should they use some disinfectant, such as carbolic acid?

DR. ERNST then replied that carbolic acid had very little effect upon the bacilli, and was hardly desirable to be used, as it would probably kill the patient, if applied in the quantity and strength necessary to affect the bacilli. The treatment of the tubercle bacillus is one that ought to be discussed and experimented upon, and the experiments be made purely from cultivations. Many of the methods of the former experiments must be radically changed.

G. L. WOODS, M.D., of Springfield, Mass., then read a paper on

THE USE AND ABUSE OF ERGOT.

He said when our countryman, Dr. Stearns, first called attention in 1807 to the scientific use of ergot as a uterine motor-stimulant, its physiological action was imperfectly understood, and even now eminent authorities can scarcely agree upon more than the one incontrovertible fact that ergot increases the force and frequency of the contractions of the uterus, with a tendency to make them tetanic in character. That it has a similar contractile effect upon all unstriped muscular fibre, which is so generally distributed in the hollow muscular organs, seems equally clear. Wernich attributes the ecbolic properties of ergot to irritation of the uterine nervous centres, caused by secondary arterial anæmia of the spinal cord, due to loss of tone in and dilatation of the veins. Kohler refers the contractions to increased irritability of the puerperal nerves in conjunction with spinal anæmia. A committee on therapeutics in the Chicago Society of Physicians and Surgeons recently reported that ergot excites activity of the cardiac inhibitory centres and also the vaso-motor nervous centres in the medulla, thereby slowing the

heart's action, causing contraction of the arterioles, increase of blood-pressure, diminution of blood-supply, and predisposing to death of the extremities. Very large doses then would seem to have a paralyzing effect upon the heart.

A knowledge of the physiological action of drugs is generally essential to their judicious administration. The most prominent action and use of a drug should not engage our attention to the exclusion of other occasional but deplorable effects. Because our text-books have always taught that, with certain precautions, ergot is innocuous in tardy labor, we are not obliged to accept the statement as a fact, if it can be shown at present or in future, that its use has not been sufficiently restricted. That such has been, and even now is the case, is the firm conviction of the writer. The use of ergot in the first stage of labor is not to be mentioned in this presence.

In view of the instruction which the average graduate has received, and the fact that he enters upon the practice of obstetrics without having seen a case of labor, but with an indefinite idea that ergot is a harmless time- and labor-saving drug, its employment in the second stage of labor becomes a radically different matter. Abundant authority for this use, however, is attested. The indications usually given, which present such a remarkably stereotyped appearance in every succeeding work on obstetrics as to preclude in the mind of the student the possibility of any other views being entertained, may be tersely stated as follows: In lingering labor from uterine inertia, it is regarded as essential that the presentation be vertex, the cervix well dilated, the perineum and ostium vaginæ relaxed, and that there be no fœtal or pelvic deformity or other obstruction to the speedy delivery of the child.

The contra-indications, as given, naturally suggest themselves; but it is the main object of this paper to express the belief of the writer, who never gives ergot at this stage of labor, but uses the forceps instead, that our authorities have been too liberal in their indications; that the contra-indications and dangers have not been fully appreciated or enumerated with sufficient fulness and clearness; that the routine administration of ergot, into which some of us fall, has been productive of great harm, and to urge its greatly restricted use. As employed by intelligent physicians to-day, rupture of the uterus is doubtless a remote danger to the mother; but if we only had access to Clay's *Handbook of Obstetric Surgery*, and gave ergot when the os uteri became dilated to about the size of half a crown, as therein directed, the prospect of a lacerated cervix would be exceptionally good. The approximately uninterrupted pressure of the head upon an incompletely dilated os is well calculated to bring about this untoward result. Clay is evidently prejudiced in favor of ergot, for he allows its moderate use in primiparæ, and bids for distinction in connection with its introduction to British obstetric practice.

Rupture of the perineum is an accident, irrespective of the use of ergot, which is occasionally unavoidable. The wonderful power of the uterine contractions under the influence of ergot is best appreciated by those whose hands have been subjected to the pressure. In proportion as ergot is used, does the distention of the perineum become unmanageable, and the liability to its serious injury increase. Too little attention is paid to the fact that in lingering labor the maternal passages are hot, dry, and unprepared for the rapid and forcible expulsion of the child. More or fewer abrasions of the mucous lining cannot fail to occur, over which the lochia must flow, and through which septic matter may be absorbed into the circulation of the mother, and prejudice her chances of recovery, while lacerations of the cervix generally escape detection until long afterward, when their ultimate effects have impelled her to consult her physician.

The writer felt that he could not too strongly urge the importance of withholding ergot during the entire period of dilatation and subsequent expulsion of the child. Exceptions will be taken to his total prohibition by men of experience, who claim immunity from accident.

Granting that these claims are sometimes well founded, the facts yet remain that ergot is daily given before the cervix is fully dilated; that rigidity and laceration often follow the sudden and continuous impingement of the head upon it; that the drug is often and repeatedly given to save time, or through deference to the wishes of the patient, and before any disproportion of diameters can be accurately ascertained. The gauntlet of impaction, the forcible passage of a large head through a small pelvis, pelvic phlegmasiæ, sloughing, septic absorption, etc., must be inevitably run. In view of all this, and more which might be pointed out, did time serve, we are confronted by this question: Do the benefits arising from this use of ergot compensate for the risk incurred?

But little notice has yet been taken of idiosyncrasy. In one case the writer has seen the ordinary symptoms of collapse follow the use of a moderate dose of ergot before delivery of the placenta, accompanied by a tonic contraction at the neck of the uterus, which effectually prevented its accomplishment for several hours. Within a few years, several similar cases have been reported in the journals, but whether this is an important factor in the production of the deplorable results sometimes following the exhibition of ergot, remains to be demonstrated.

Considering the action of ergot upon the circulatory system, an enfeebled or diseased heart would appear to be a contra-indication, which is universally ignored.

Though abuse may grow out of the use of the forceps, as well as of ergot, their employment presents marked advantages over the latter. A case which is suitable for ergot admits of their application; the liability to lacerations is materially lessened; the progress of the child is under control, the risk of asphyxia is obviated, and its safety is assured. The danger to the child can no longer be underestimated. Whether a poisonous effect is produced, as has been claimed, cannot yet be definitely stated, but the tendency to tetanic contractions with prolonged pressure upon the placenta or funis seriously interferes with the oxidation and decarbonization of the fœtal blood, and imperils the life of the child. If Churchill[1] be followed, who allows ergot to be given when the breech presents, how can this danger fail to be materially increased when the placenta is firmly compressed between the unyielding head and the uterine wall?

Spiegelberg insists upon the necessity of carefully observing the fœtal heart after the use of ergot, in order that the forceps may be immediately resorted to in threatened asphyxia. That this is often done may well be doubted.

Benicke reports twenty-seven cases in which ergot was given during the second stage on account of uterine inertia. Spontaneous delivery occurred in but seven of these cases.

It should be axiomatic with every practitioner that economy of his own time never justifies the use of ergot, but beyond every private and selfish consideration he cannot escape the responsibility imposed by a knowledge of its unreliability, its manifold dangers, and the frequent necessity for instrumental interference.

It is after the uterus has been completely emptied of

[1] System of Midwifery.

its contents and for a varying degree of time after delivery then that ergot, in the opinion of the writer, meets its proper and strongest indication. No physician should attend a case of labor without having ready to hand hot water and a solution of ergotine, with appropriate syringes prepared for instant use should hemorrhage occur after complete evacuation of the uterus.

Post-partum hemorrhage is thus robbed of half its terrors. One of the most frequent indications for the use of ergot is subinvolution of the uterus. It has long seemed to the writer that appropriate prophylactic treatment, provided it could be applied, would greatly reduce the number of these cases. This treatment, which is found to be impracticable without the hearty coöperation of the patient, should begin from the moment the third stage of labor is completed. At this time, when the uterus has thrown off the burden which it has carried for nine months, the organ weighs, according to Heschl, from twenty-two to twenty-four ounces, and its length, according to Bærner, who has measured it in sixty-four cases, averages four inches. At the end of the first week, at which time women often get up, the uterus weighs from nineteen to twenty-one ounces; at the end of the second week from ten to eleven ounces; at the end of the third week from five to seven ounces; and the nearest possible approach to the normal weight of about two ounces is not reached until the close of the second month. The new mucous lining of the organ does not form before the third week. We must dissent then from the views of an eminent writer if, as reported, he advocates the encouragement of the patient to rise and dress on the third or fourth day after delivery in ordinary cases. The writer ventures the opinion that this time for keeping the bed or lounge is much too short. Indeed, the time-honored period of nine days does not seem long enough. At this time, even although the bulk of the uterus is much reduced, we have seen that it yet remained enlarged, soft, congested, and too heavy for its relaxed supports. Walking, standing, lifting, pelvic inflammations, etc., contribute to retard the process of involution, in many cases entirely arresting it short of completion, when we have resulting the condition of subinvolution, the grand predisposing cause of that long train of symptoms so familiar to the physician. Have we not here a clear indication for prophylaxis? The patient should not only be kept longer in bed to facilitate involution, but we shall do well to remember that it is the soft, spongy, subinvoluted uterus for which Bartholow recommends ergot. Believing that the process of involution is materially aided and advanced by the cautious use of ergot, it is the practice of the writer to give it in moderate doses for some days after delivery.

Corroborative evidence of the value of this plan of treatment is not yet abundant, but Dr. Garrigues, of New York, may be briefly quoted upon the use of ergot as follows: "ergot ought never to be given during labor. I use this drug in every labor, but not until after the placenta has been expelled. I give it even for four or five days, because I think that by causing contraction of the muscular coat of the bloodvessels, it counteracts absorption of septic matter, and by increasing, uterine contractions insures good involution."

Dr. W. A. Dunn, of Boston, then followed in a paper on the same subject.

Afternoon Session.

Dr. J. W. Warren, of Boston, read a paper on

Glykogen.

He said: Of all the bodily organs common to both sexes, no one perhaps has attracted the attention of the medical profession so constantly and so universally as the liver. One other organ, the uterus, has been a worthy rival. We are still far from knowing with any exactitude what the liver—or indeed almost any organ of the body—really does. But we have taken the first great step at least on the road to knowledge. Much that is done is published in journals or pamphlets not very accessible to the general practitioner. I have ventured, then, to ask your permission to-day to act as a modest filter in presenting as concisely as may be some of the results of work done by many authors in the past few years, and bearing upon one function of the liver—I mean its glykogenic function. We are accustomed, nowadays, to think of glykogen. There are members enough of this Society, still hale and hearty and in busy practice, who never heard of any such substance until they had been in active work for years, when the discovery was made that the liver contained a starch-like body which, under certain conditions, is changed into sugar, and this discovery is associated with the name of the great Frenchman, Claude Bernard. Bernard had found sugar in the liver, and had described its production as a new hepatic activity, so that when yet another new liver substance was found, capable of easy transformation into sugar, the name of sugar-former, or glykogen, was naturally suggested. Circumstances have combined to attract much attention to its study. Physiologists have long recognized that the glykogen problem has far more importance than the explanation of such a disease. The whole problem of nutrition is very far from a solution.

The chemical story of glykogen can be very briefly told. It is, when dry and pure, a white powder, perfectly amorphous, showing nowhere the least tendency to crystallize. It is soluble in water, at least it seems to go into a solution of a peculiar opalescent character. It rotates the plane of polarized light to the right, three or even four times as much as glucose. The opalescent solution can be cleared by the addition of an alkali or an organic acid, but it is probable that a modification of the glykogen is brought about by this treatment. It is precipitated by alcohol and by ether. The ordinary method for obtaining glykogen is simple, and for its best form we are indebted to Brücke. The tissue to be treated is to be minced as fine as possible and extracted in hot water, as long and as often as anything is taken up. The filtrate is then freed from such albuminous bodies as have passed in the hot solution, and the glykogen is precipitated by alcohol, washed, redissolved, and again precipitated, until the desired degree of purity has been attained.

It is usually considered easy to obtain perfectly pure glykogen, free from salts that is, and leaving no ash upon combustion. But there is apparently a discrepancy in the statements, for only a few weeks ago a careful worker in this department reported that he found perfectly pure glykogen, which he had very carefully prepared, to remain in solution despite the addition of a considerable amount of chloride of sodium, which caused a complete precipitation. Under the influence of various acids, and particularly of numerous ferments, glykogen becomes more or less changed, and these changes can, to some extent, be traced by the behavior of the body to iodine. Within a few years it has been shown that the action of the ferments on glykogen produces a sugar not unlike glucose, and yet different enough to be of importance.

The exact chemical composition of glykogen is not certainly known—it belongs to the carbohydrates, *i. e.*, it contains only carbon, oxygen, and hydrogen; these latter in the same proportions as water. Hoppe-Seyler gives it the formula, $C_6H_{10}O_5$.

If we were to name the sources from which we can obtain glykogen, it would be necessary to mention not only most all the tissues of the vertebrates, but we should have to include many other forms of animal

life. Such a thing as vegetable glykogen has been found; a fact, too, that has never received the attention it probably deserved. It interests us especially to remember that the mammalian liver and muscular tissues contain very considerable amounts of glykogen, and this is true not only of the developed animal, but also of the newborn which have not yet received any nourishment save through the uterus or in the egg. The presence of glykogen in the muscle is no new discovery. The percentage of glykogen found in muscular tissue is small as compared with that of the liver; but if you will take the trouble to figure it out, you will find that the total amount in all the muscles is oftentimes not very much less than that found in the liver. That this is actually true was demonstrated some three years ago by Boehm. The coagulated muscle-tissue retains the glykogen, it being much more difficult to prepare it for extraction than the softer tissues of the liver. In view of this fact—and I see no reason to question the trustworthiness of Boehm's statements—it is clear that all previous observations on the quality of muscle-glykogen, and its behavior under various influences, are subject to very considerable doubt. The form in which glykogen is stored up in the muscles is unknown.

Concerning the conditions which favor the increasing of the glykogen in the liver or the muscles as well as the conditions favoring its disappearance. There is unfortunately much disagreement despite the very large number of experiments reported. On one point, however, there is a general unanimity that feeding increases, while hunger distinctly decreases the amount of glykogen; among the foods, those containing sugar or whose digestion produces much sugar, have seemed especially efficacious.

The influence of the carbohydrates admits of various explanations. The glykogen might be formed directly from them by some synthetic process which prepares it to be stored up until wanted, or the carbohydrates might take the place of the glykogen already in the liver, and being constantly stored up there, but only to be normally carried off again nearly as rapidly. In this case it will be seen that an increase of the glykogen could take place, running parallel with the inflow of the carbohydrates. Yet another simple explanation offers itself. A portion of the carbohydrates may be changed directly into glykogen, the remainder being worked up otherwise, and acting in some way as a stimulus to the formation of glykogen out of other substances.

Not a little of this difficulty has been occasioned by the very natural view that the liver-sugar came directly from the glykogen; sugar is found in the liver, and its increase after death has long been known, and a decrease of glykogen has been postulated on, even seemed to be shown to be associated with this change. It has also been clearly shown that the development of sugar in the liver, as a post-mortem change, is the development of grape-sugar, and is not associated with a diminution of the glykogen, or at least that the disappearance of the glykogen bears no relation to the development of sugar.

Of greater importance still is the demonstration, that the liver is capable of forming sugar out of albuminoid material. This alteration of albuminoid material seems to be a distinct function of the liver, a function then, which is carried on independently, it may be, of the glykogen present.

Of the value of glykogen to the muscle but little is known. We know, as already mentioned, that large quantities are found in muscular tissue after feeding, and that hunger caused a marked diminution of the quantity. Boehm, however, found that rigor mortis itself is not necessarily associated with a lessening of the glykogen if putrefactive changes are avoided. If we wish then to summarize briefly, we may say the presence of glykogen is closely associated with the first steps of nutrition.

One point should not be left out of sight, and that is this: That wherever the disappearance of any putrefactive change can be assumed, we shall find a marked diminution of glykogen, and it becomes a serious question how far the disappearance of glykogen, as reported in all earlier investigations, has been due to some putrefaction—in other words, has not been merely functional.

DR. O. F. WADSWORTH, of Boston, then read a paper on

PHLYCTENULAR DISEASE OF THE EYE.

He referred to the multiplicity of names which have been given to the affection, some of them misleading, as implying analogies which do not exist, the result being to make the general understanding of the disease more difficult than it need be. To a certain extent the same effect is produced by the habit of treating separately of conjunctival and corneal disease. The disease is essentially the same whether it involve conjunctiva or cornea. It is characterized by the eruption of vesicles or pustules on conjunctiva or cornea, or on both, and often attended by very troublesome blepharospasm. The frequency of the disease is very great, it is mainly confined to young children, and often leads to permanent impairment, or even to loss of sight. It is often obstinate, and tends to recur on slight provocation, yet the importance of the trouble is not generally appreciated by the laity. The various forms which the eruption may present was described, and the different degrees of danger, as cornea or conjunctiva is implicated, pointed out.

The so-called photophobia may be excessive, but is not by any means always in accord with the severity and danger of the disease. Some of the worst forms have the symptoms but little pronounced The true scrofulous ophthalmia is in many cases not properly applicable, yet it suggests the direction in which the cause is to be sought, *i. e.*, a condition of health below the normal. Such exposure as excites catarrhal affections of the mucous membrane of the throat and nostrils is an exciting cause, as are indirectly the exanthemata. The prognosis can usually, at first, be only a provisional one on account of the inclination to relapses and recurrence. General treatment is of the highest importance; nourishing food, bathing, fresh air, light, and tonics. Blepharospasm, so-called photophobia, is excited by the irritation of the terminal branches of the trigeminus, not by hyperæsthesia of the retina. The indication is to relieve the hypersensitiveness of the cornea, and atropine offers the best means. Eczema of the lids and face is a frequent accompaniment, and demands appropriate treatment. Irritants are to be avoided. Success in treatment depends on attention to details.

Local treatment consists in the use of mild collyria, atropine, and the careful application of calomel, which latter should never be employed when iodine is given.

Astringents are in general to be rejected, yet when there is the complication of a catarrhal conjunctivitis they may be used with caution. For the sluggish infiltration of the cornea hot fomentations are of benefit, The many means recommended for promoting absorption of corneal opacities left by the disease are of little value.

DR. B. HARTWELL, of Ayer, also read a paper on

MINOR INJURIES OF THE SPINAL CORD,

which was based upon the notes of nine cases, in which both the injury and the force used to produce it were slight, five of the nine were passive or subacute hy-

peræmia, and four a mild form of chronic myelitis. They were of from two to twenty years duration, and were not severe enough to prevent a certain amount of labor being performed.

These minor injuries are of special importance to us as practical physicians, from their comparative frequency, their liability to result in permanent changes in the substance of the cord, and because we can do much in the way of relief and cure by appropriate treatment.

After stating their importance in a medico-legal point of view, he approvingly quoted Hodges' view in regard to the positiveness of the symptoms in spinal concussion, and also the generally favorable prognosis in such cases. He gave the history of two cases of spinal concussion from railroad accidents, in which the symptoms were not developed until four and ten days after the injury, followed by very good recovery.

The author then passed to cases caused by jar of railroad carriage, and reported two cases of passive or subacute hyperæmia, one of the cervical, the other of the lumbar enlargement of the cord of six to twelve years standing, which were finally compelled to seek relief. He then gave the history of two cases of injury of the lumbar enlargement of the cord, by way of illustrating the larger number of those minor injuries of the cord, caused by concussion, blows, or other means, in which there is no external sign of injury, and the patient is able to attend in part to daily duties. These are transverse lesions of the cord, and are either subacute hyperæmia or a mild form of chronic myelitis, the line between them being an artificial one.

The diagnosis of these cases in the early stages is often difficult when only backache is present, with perhaps neuralgic-like pains extending into the legs, simulating sciatica.

The points in diagnosis are tender points along the course of the nerve in the latter, which do not occur in the former, the recumbent position aggravates pain in cases when there is increased circulation in the cord, the history of injury to the back, and finally trial of remedies: Strychnia increasing the pain and other symptoms of myelitis and hyperæmia, ergot and belladonna relieving them.

The prognosis is usually good; some of the cases getting entirely well, others remain greatly relieved, and occasionally one relapses into a hopeless case of chronic myelitis; in these latter, the change is usually sudden; as a rule, the cases are worse in hot weather, and are made temporarily worse by hard work or active exercise.

The recent cases of injury are treated by digitalis, aconite, bromide of potassium. Ergot usually aggravates, as is shown by Bartholow in a clinical lecture in THE MEDICAL NEWS of December 16, 1882: "Its administration in acute spinal inflammation is improper, because of the peculiarity of its action, it induces an anæmia of the arterial distribution"—an ischæmia properly speaking—but the blood thus driven from the arterial side accumulates on the venous side.

Hot douches and mild irritation of the spine do good in all cases. In the chronic form ergot and belladonna in full doses, dry cups along each side of the spine night and morning, galvanism, rest, not absolute, but with moderate exercise, are the remedies upon which we most rely. Belladonna gives most immediate relief from pain, and acts best in cases in which the bladder is involved.

PROF. T. M. CLARK, of the Institute of Technology, then made some interesting remarks on

PLUMBING APPLIANCES.

He said: You will hardly expect me to say anything here about the long list of diseases attributed to the inhalation of sewer gas. Independent, however, of this question, there is another branch of inquiry which seeks to know how far the appliances now in use accomplish this result. In the discussion of this subject, the experience of the architect ought to be of some small service, for no one except a plumber or an engineer is kept more constantly in the current of the new inventions, and no one has a better opportunity for trying those which he may see fit to adopt. Some defects they all have, but improvements are made every day, the value of which is best appreciated by recurring to the developments of the more important inventions.

We shall find that great changes have been lately made in the design of conduits. In the primitive form of drain, the straight pipe extending from the sink or other receptacle of wastes in the house to the vault or cesspool outside, the lining of decomposing slime soon becomes objectionable. With the introduction of porcelain fixtures, it became apparent that something was still wanting to the success of the system, and attention was turned to the trapping. It was discovered that in the descent of a considerable quantity of water down a main drain-pipe, a partial vacuum was left behind it, into which the air from outside would press with sufficient force to push out easily the little column of water in the traps. The water being thus removed from the traps, left them open flues for bringing air from the soil-pipes into the cistern. The remedy for all these troubles, caused by the exhaustion of air in pipes behind moving bodies of water, was to break the "siphon" by the admission of air.

The adoption of improvements was followed by some unexpected good effects. The uniting of traps is a somewhat expensive matter, since the length of the waste pipes is nearly doubled, and many attempts have been made to avoid it by the use of anti-siphoning expedients. However the system of pipes and traps may be managed, it is essential that all joints should be tight.

We need to know as much as this about the general methods of managing waste-pipes before we can appreciate some of the better points in the modern auxiliary apparatus. We find that the improvements within the last few years have been quite as great as in the system of pipes and trapping. It is not long since the ordinary appliance under this name consisted of an iron hopper, painted or enamelled inside, furnished with an iron trap at the bottom. This closet, when properly kept, was not so bad as some that have succeeded it. The main objection to it was that the bowl did not contain any water, and was liable to streaks and stains, until the contents accumulates in it to such an extent as to prevent the pan from moving. The operation of the closet is not interfered with, but the putrescent mass, of course, gives off its appropriate odors, which escape into the room in clouds whenever the pan is opened, and leak in slowly at all other times. It was obvious enough that the abolition of the filthy contents would be the next improvement in water-closets, but this was not accomplished at once. The first step was to reduce its size. In this way a large volume of water could be kept in the bowl. To facilitate this, the whole space from the outlet of the bowl to the valve is, in the best closets of this kind, kept as smooth as possible. Another novel mode of accomplishing a similar result was introduced in the Jennings' closet. The Jennings' closet consisted in a hopper with the outlet bent literally so as to admit of closing it by a gate or plunger, which serves to retain the water at a height in the bowl limited by an overflow. The difficulty, however, of insuring the attention necessary to keep this closet in order resulted in endeavors to produce a simpler apparatus. The most

successful devices for this purposes have all taken their origin from the ancient hopper, which, while preserving its simplicity of form and freedom from moving parts, has been improved by the addition of a full and well-directed flush of water into the best appliances.

The modern hoppers, instead of being enamelled or painted iron, are all of white glazed earthenware. In order to secure the flush which is essential and which distinguishes the modern from the ancient hopper, the water is introduced all around the rim instead of at one point. The contents of the bowl are driven straight through this trap. In the hopper hitherto made, however, the trap is set so low that the water-line in it does not rise higher than its lower outlet. The amount of defilement is so slight as to produce little or no real annoyance, but in a good house every suggestion of foulness is to be avoided. A demand has recently arisen for a form of closet which should combine the advantages of the flushing rim hopper with the further one of retaining in the bowl a sufficient quantity of water to receive the soil without allowing it to touch the glazed surface.

With respect to other appliances, the same tendency to the substitution of vitrified materials for metals is to be observed in kitchen and other sinks, which were formerly used in good houses, of wood, then of iron, are now very generally made of soapstone, and they will before long be replaced by glazed earthenware.

In the modern habitation there must be no holes for refuse, and the sinks of the present day stand on iron or wooden legs, entirely open to the room. Water-closets are now very commonly set in the same manner. It is certainly true that the smallest vestige of the stenches which were once considered indispensable to domestic life, are now pursued with relentless vigor by those who know how to deal with them. Ten years ago it was the custom to make a single pipe do for several fixtures, running, for instance, the waste-pipes of the bath-room into the trap of the water-closet. This left a certain length of waste-pipe free to collect slime on the inside surface and to transmit the gases engendered by the decomposition of the slime back into them. The return of corrupted air from the short lengths of the house-wastes is quite incompatible with the new ideas, and every fixture is now, in good work, trapped as close as possible to the outlet. In addition to this, good modern work provides for the circulation of outdoor air through the whole system of drain- and waste-pipes.

The next improvement in house-drainage will probably be the provision of ventilation pipes, by which air will be constantly drawn out of bath-rooms and closets through the strainers and overflowers of the various kinds of apertures ventilating the apartments in which they are placed.

It cannot be doubted that the householders of the future will demand a degree of purity in the atmosphere of their homes of which we know little as yet; and no one who has lived in rooms where the air is constantly changed, will willingly submit to breathe again the exhausted and tainted atmosphere which now pervades the majority of dwellings.

WEDNESDAY, JUNE 13TH, SECOND DAY.

THE SECRETARY'S REPORT.

THE SECRETARY, DR. F. W. GOSS, read the records of the last annual meeting, and announced the names of the Fellows who had been admitted to the Society during the year—about ninety in number. He then read the names of twenty-seven deceased Fellows, whose average age was 60⅓ years.

THE TREASURER'S REPORT.

THE TREASURER, DR. F. W. DRAPER, then presented his annual report, which showed an income of $8,595.79, an outgo of $7,056.37, and a balance in the treasury of $1,539.42. The invested funds amount to $32,420.17, and remain unchanged, and yield four per cent. The treasurer announced that, owing to the energetic action of the District Treasurers, the list of delinquents was smaller than ever before, notwithstanding the large accessions to the Society.

THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE.

On motion of DR. H. P. BOWDITCH, of Boston, it was voted that a committee of three be appointed to memorialize Congress in regard to the disposition and care of the Library of the Surgeon-General's Office, and urge upon our Representatives the importance of providing a fire-proof building for its preservation in connection with the Museum, and distinct from the general Congressional library; also to memorialize Congress to make a liberal appropriation for the completion of the *Index Catalogue*, and for the general purposes of the library.

The Chair appointed as the committee under the above resolution, Drs. H. P. Bowditch, H. P. Wolcott, and O. F. Wadsworth.

The request of the President of

THE COLLEGE OF PHYSICIANS AND SURGEONS,

that diplomas granted by the College be recognized by the Society, was, after some discussion, laid on the table.

DR. E. N. WHITTIER, of Boston, then read a paper on

RECENT CHANGES IN THE METHOD OF MEDICAL INSTRUCTIONS.

He briefly reviewed the old system of acquiring a knowledge of the science of medicine by studying with some physician. He said that the method was unsatisfactory, and the practice of medical apprenticeship was practically abolished and superseded by the co-operative system of instruction, students having advantages in class instruction by different lecturers and professors which they could not have while studying with one physician. The rapid growth of hospitals requires a larger number of under-graduate appointments, and the difficulty is not to get enough but to select from those fitted for the positions, showing the high standard of students in medical colleges. He then considered some points in the present system of instruction which he thought might be improved.

DR. J. S. GREENE, of Dorchester, then read a paper on

NEURASTHENIA: ITS CAUSES AND ITS HOME TREATMENT.

He said it was not work, but competition, anxiety, hurry, and excitement of business and society, not education, but cramming, that causes nervous exhaustion. He then spoke in detail of the influences resulting in nervous exhaustion, and considered the different methods of treatment, paying a high tribute to those who have endowed hospitals for the reception and treatment of persons suffering from "neurasthenia."

DR. J. W. SPOONER, of Hingham, then read a paper on

THE ARTIFICIAL FEEDING OF INFANTS.

The different forms of food he placed under three divisions:

1. Milk of some other animal.
2. Condensed milk.
3. Prepared foods.

1. Milk of some other animal.—The ideal infant's food is the breast-milk of a healthy woman. In its absence, we must get a milk that resembles, as nearly as possible, human milk. That of the cow is generally used because it can be easily obtained, although the milk of the ass, the mare, and the goat, in chemical composition, resemble breast-milk more closely.

Different examiners have reached contrary results in the analysis of human milk. After an examination of different tables, the writer concludes that the often-quoted tables of Vernenil and Becquerel are incorrect in this respect that they make the amount of caseine too large, and that of sugar too low.

The results of Henri and Chevallier and those of Arthur V. Meigs are thought to be more correct.

These tables show that human differs from cow's milk in containing much less caseine and more sugar. The slightly acid reaction of cow's milk, first stated by Parker, and again by Meigs and Pepper, was confirmed by an examination of the freshly drawn milk of nine pasture-fed cows, the milk in all these cases being faintly acid.

To make cow's milk suitable for the new-born child, it must be rendered alkaline, diluted with double the amount of water, and sweetened, preferably with milk sugar, and a tablespoonful of cream added to each nursing. Where hard curds are formed in the infant's stomach, even after dilution, the writer has found a solution of Irish moss, used in place of simple water, to act well in breaking up these cheesy masses.

2. Condensed milk is often a useful diet for children under three months. After this age, children fed upon condensed milk, although they may seem fat and well, yet fail to develop strong muscle and bone. The food seems lacking in albuminoids.

3. Prepared foods.—The test by which such articles of diet must be judged is the comparative absence of crude starch. Children less than six weeks old change starch into sugar slowly and imperfectly. Mellin's food has been found by the writer to be better than any preparation of this kind that he has used.

In conclusion, the following list meets the approval of the writer:

1. Diluted milk, and under this head the preparation recommended by Dr. Arthur V. Meigs (THE MEDICAL NEWS, November 4, 1882) deserves careful attention.
2. Mellin's Food.
3. Milk diluted with a solution of Irish moss or gelatine.
4. Condensed milk.

DR. W. B. GOLDSMITH, of Danvers, then read a paper on *The Early Symptoms of General Paralysis of the Insane.*

The following named

DELEGATES FROM OTHER STATE SOCIETIES

were then introduced to the meeting: Drs. F. W. J. Prey and L. I. Young, of *Maine;* E. R. Campbell and Robert Dinsmore, of *Vermont;* G. T. Swartz and H. J. Miller, of *Rhode Island;* G. G. Hopkins, P. V. S. Pruyn, and E. N. Brush, of *New York;* and Alice Bennet, of *Pennsylvania.*

After an intermission of fifteen minutes,

THE ANNUAL DISCOURSE

was delivered by AMOS H. JOHNSON, M.D., of Salem. He referred to the wonderful progress made in the study of astronomy and electricity during the last few years, and then turned to the consideration of the progress in the science of medicine, saying it was chiefly the result of judgment and critical observation. He spoke of the danger of allowing patients to follow Nature as a guide, declaring that in many instances her advice proves fatal, and physicians must take the guidance of Nature's control over his patients. The indifference with which the presence of some contagious diseases is regarded is one of the moral influences which has to be met. The science of preventive medicine is of recent growth, but facts acquired are of great value. He expressed the hope that the time would come when the State Board of Health would be relieved from the fear of political influences and attain its greatest usefulness.

Nature cannot be relied upon to best interpret her suggestions. Careful study of the results obtained by the investigations of others is necessary. Observation is not interpretation—to see is not to learn.

At the conclusion of his address a vote of thanks to Dr. Johnson was passed.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—Alfred Hosmer, M.D., of Watertown.
Vice-President.—Ira Russell, M.D., of Winchendon.
Treasurer.—Frank W. Draper, M.D., of Boston.
Corresponding Secretary.—C. W. Swann, M.D., of Boston.
Recording Secretary.—F. W. Goss, M.D., of Roxbury.
Librarian.—David H. Hayden, M.D., of Boston.
Orator for Anniversary in 1884.—John Crowell, of Haverhill.

THE ANNUAL DINNER of the Society was served at 1 P.M., in the skating-rink on Clarendon Street, Francis H. Brown, M.D., of Boston, presiding.

NEWS ITEMS.

CLEVELAND, OHIO.

(From our Travelling Correspondent.)

THE AMERICAN MEDICAL ASSOCIATION has adjourned for this year, and the majority of the members have already started for their homes. Upon the whole, it has been a very pleasant meeting, and the great majority of those present seem to have thoroughly enjoyed their week's vacation. It is true that the hotel accommodations were insufficient for so large a gathering, and that in consequence some of the members could not obtain comfortable accommodations; but their graphic accounts of their discomforts were for the most part given with great good-humor to small and laughing audiences, and everybody was disposed to make the best of the situation.

Cleveland is very justly counted as one of the five most beautiful cities of the United States, her characteristic features being indicated by her sobriquet of the "Forest City," and during this week the foliage has been very near perfection. A stroll or drive down Euclid Avenue or Prospect Street, at this time of year, is a special pleasure to those who can appreciate without envy the beautiful homes which line these favorite promenades, with their spacious lawns. About twenty of these homes were opened for receptions in honor of the Association on Wednesday and Thursday evenings, and these were thoroughly enjoyable and enjoyed.

You have received full accounts of the literary and scientific work of the Association, which was about up to the usual standard. The most important topics of conversation were the New York Code of Ethics, and the proposed New Journal of the Association, yet comparatively little was said about either. No one wished to discuss the Code—the feeling being almost unanimous that this is no time to propose changes.

Some stir was made by a paper read by Dr. A. L. Gihon, U S. Navy, in the Section on State Medicine, in which he expressed, with more energy than discretion, a quasi-contemptuous feeling for the old Code,

and an admiration for the new. When it became known that the author of this paper, who was one of the Nominating Committee, was to be nominated as one of the vice-presidents of the Association, there was a very general feeling of dissatisfaction, and the matter came up in the Committee in the form of a resolution to reconsider the nomination. The matter was finally settled by Dr. Gihon's signing a paper, declaring his unqualified adherence to the old Code, which paper was read in connection with his nomination, and probably prevented the presentation of protests and the reference of the matter to the Judicial Committee.

The Council seems to have had very little to do, almost the only matter adjudicated being the case of Dr. Goodwillie, of New York, who had written a letter to the Chairman of the Committee of Arrangements, declaring his rejection of the old and his adhesion to the new or New York Code, whereupon protests against his being allowed to register were presented by delegates from the New York Academy of Medicine.

It seems that Dr. Goodwillie was allowed to register, inasmuch as he had signed the application made by all delegates upon which was the following statement:

"In acknowledgment of having adopted the Constitution, By-laws, and Code of Ethics of this body, and of my willingness to abide by them, and use my endeavors to carry into effect the objects of this Association, I hereunto affix my name."

The Doctor, however, claimed that he had signed this under compulsion, and did not consider it as binding upon him, so far as it was in conflict with the New York Code. The decision of the Council was that his name should be cancelled from the registry-list, and his money be returned to him; and the essential point upon which his case turned appears to have been that he did not confine himself to criticising or expressing an unfavorable opinion of the Code of the Association, which every one has a right to do, but that he formally declared that he did not intend to abide by it.

The nomination of Dr. Flint appears to give very general satisfaction, although many of the Southern members claim that the Presidency should have been given to Dr. H. F. Campbell, of Georgia, and the claims of this gentleman were strongly urged in the Nominating Committee.

Everybody is glad that the next meeting is to be in Washington, which is recognized by all as the proper place to be made, what might be called, the home-centre of the Association, and the only doubts expressed are as to whether sufficient hotel accommodation will exist in the latter part of the long session of Congress.

As to the forthcoming journal, every one is willing to see the experiment tried, but few are sanguine as to its success under existing conditions. It will be tolerably plain sailing for the first few months so far as quantity of material is concerned, at least, but after that will come the rub. However, we all wish it success.

RESIGNATION OF PROFESSOR WALLACE.—PROF. ELLERSLIE WALLACE has resigned the Chair of Obstetrics and Diseases of Women and Children in the Jefferson Medical College on account of ill-health. His successor has not as yet been elected, but the following gentlemen have been nominated for the vacant chair, at a meeting of the Trustees held last Monday evening: Drs. A. H. Smith, Ellwood Wilson, and F. H. Getchell, of Philadelphia; J. C. Reeve, of Dayton, O.; Theophilus Parvin, of Indianapolis; and E. W. Jenks, of Chicago. The election, it is understood, will be held on June 25.

PROF. PORRO has resigned his chair in the University of Pavia, and has been nominated as Director of the School of Obstetrics in Milan.

THE MASSACHUSETTS MEDICAL SOCIETY AND WOMEN MEMBERS.—The Councillors last Tuesday, at the annual meeting, refused by a vote of 62 to 58 to admit women to membership in the Society.

NEW JERSEY STATE MEDICAL SOCIETY.—The One Hundred and Seventeenth Annual Meeting of the Medical Society of New Jersey was held at Atlantic City, on June 12th and 13th, and the following officers were elected for the ensuing year:

President.—Stephen Wickes, M.D., of Orange.

Vice-Presidents.—P. C. Barker, M.D., of Morristown; Joseph Parrish, M.D., of Burlington; Charles J. Kipp, M.D., of Newark.

Corresponding Secretary.—William Elmer, Jr., M.D., of Trenton.

Recording Secretary.—William Pierson, M.D., of Orange.

Treasurer.—W. W. L. Phillips, M.D., of Trenton.

Standing Committee.—Drs. T. J. Smith, of Bridgeton; Samuel S. Clark, of Belvidere; E. J. Marsh, of Paterson.

The next meeting will be held at Cape May, on the second Tuesday in June, 1884.

THE STATE MEDICAL SOCIETY OF DELAWARE.—At the annual meeting of this Society, held at Wilmington, on June 12, the following officers were elected for the ensuing year:

President.—Robert M. Hargadine, M.D., of Felton.

Vice-President.—Willard Springer, M.D., of Wilmington.

Secretary.—George W. Marshall, M.D., of Milford.

Treasurer.—J. W. Sharp, M.D., of Camden.

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending June 2, 1883, indicate that scarlet fever, mumps, and erysipelas have increased, and that pneumonia, bronchitis, and diphtheria have decreased in area of prevalence.

Compared with the average for the month of May in the preceding six years, measles was much more prevalent, influenza was more prevalent, and intermittent fever and consumption were less prevalent during the month of May, 1883.

Including reports by regular observers and by others, diphtheria was reported present during the week ending June 2, and since, at fifteen places, scarlet fever and measles each at thirty-seven places. One case of smallpox was reported in Lyons Township, Ionia County, June 6.

OFFICIAL LIST OF CHANGES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 4 TO JUNE 11, 1883.

MCKEE, J. C., *Major and Surgeon.*—Assigned to duty as Post Surgeon Presidio of San Francisco, Cal.—*Par. 2, S. O. 56, Department of California, May 25, 1883.*

DE LOFFRE, A. A., *Captain and Assistant Surgeon.*—To proceed to Madison Barracks, N. Y., and report to the Post Commander for duty.—*Par. 2, S. O. 98, Department of the East, June 5, 1883.*

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL ARTICLES.

PEMPHIGUS, AND THE DISEASES LIABLE TO BE MISTAKEN FOR IT.

BY GEORGE H. ROHÉ, M.D.,

PROFESSOR OF HYGIENE AND CLINICAL DERMATOLOGY, COLLEGE OF PHYSICIANS AND SURGEONS, BALTIMORE; MEMBER OF THE AMERICAN DERMATOLOGICAL ASSOCIATION, ETC.

(*Read before the Medical and Surgical Society of Baltimore.*)

IN 1877 I was asked by a medical friend to see with him a patient in whose case he was unable to arrive at a satisfactory diagnosis. The patient was a white woman, about fifty years of age, born in Ireland, but a number of years resident in this country. She had been inoculated in Ireland with smallpox virus, and passed through a mild attack of the disease at that time, the scars of which remained as evidences of the truth of her statement. About a year before I saw her, my *confrère* had attended her in an attack of smallpox of considerable severity, being the second attack, including the one following the early inoculation, that the patient had passed through.

About ten days before I was asked to see the patient, she had been attacked by the prodromic symptoms of smallpox, followed after the usual interval by an eruption of papules, rapidly developing into pustules of large size. At the time I saw her, the entire body was covered with pustules, varying in size from a pea to a hen's egg, many of them being black from effused blood. Some of the blebs had been ruptured, discharging their contents, and leaving an uneven, ragged, necrotic-looking base, a portion of the dermal structure being evidently destroyed. There was considerable inflammation and swelling of the skin present. The patient was much prostrated, and gave all evidences of grave systemic involvement. After a thorough examination of all the circumstances, I gave it as my opinion that the patient suffered from smallpox, in spite of the fact that she had passed through two attacks of the same disease before—one (the first) according to her own testimony, supported by the evidence of the scars remaining, and the second under the care of a thoroughly competent physician, whose experience with smallpox had been gained in an epidemic of wide extent and severity a few years before. The patient died a few days after I saw her, of exhaustion.

On March 6, 1883, I was called by my friend, Dr. R. H. P. Ellis, to a case presenting somewhat similar difficulties of diagnosis. The case was that of a robust carpenter, twenty-six years of age, who consulted Dr. Ellis some days before, with a peculiar bullous eruption upon the hands and face. In view of the fact that the patient lived in a smallpox-infected part of the city, the latter disease was, of course, first thought of; but Dr. Ellis, being solicitous of doing no injustice to his patient, even at the sacrifice of some time and convenience to himself, examined him very carefully before venturing a positive diagnosis. The examination convinced him that the case before him was not smallpox, or else that it was a very unusual and anomalous form of that disease. He therefore kept the patient under observation, treating him expectantly. The doctor noted the frequent eruption of bullæ, appearing in crops, and varying in size from a bean to a large almond. The bullæ were tensely filled with a clear, yellowish fluid, the walls of the blebs springing up abruptly from the sound skin, which presented no traces of inflammation or swelling. In a few days, the fluid contained in the blebs was absorbed, and the roof dried into a thin, brownish scab, which soon fell off, leaving a reddened, but not exuding surface beneath. The blebs appeared in crops; as fast as a number had disappeared, new ones appeared, passing through the same stages of development. If the bullæ were punctured with a needle, the fluid escaped, and they collapsed and dried up, looking for a time, however, very much like a flattened variolous pustule.

When I saw the patient, this eruption extended over the entire body, discrete for the most part, but confluent in places. Especially about the genitals was a large patch, very much resembling a patch of confluent smallpox pustules. There was considerable fever present on the day I saw the patient, but very little other evidence of serious constitutional involvement. He was cheerful; strong enough to walk about; slept well, and had a good appetite.

In this case, the diagnosis appeared to me equally plain as in the other. Considering all the symptoms, and not merely the eruption on a limited portion of the body, which might, and doubtless would, mislead many practitioners who failed to seek further, I gave a diagnosis of pemphigus, and advised the treatment most appropriate, viz., large doses of arsenic.[1]

These two cases, especially interesting in view of the consequences involved in an incorrect diagnosis, have led me to direct your attention this evening, as briefly as practicable, to the principal points of difference between pemphigus and such eruptions as might readily be mistaken for it.

Pemphigus is a disease of the skin, characterized by the outbreak of blebs, varying in size from a small bean to a hen's egg, or larger, generally appearing in crops, and accompanied by more or less febrile disturbance.

This definition sufficiently characterizes pemphigus, and marks it as a disease standing by itself. It

[1] The patient has entirely recovered under the arsenical treatment, which is claimed by such an accurate observer as Hutchinson to be specific in pemphigus.

is not merely an eruption of blebs, but successive crops of these blebs appear. The blebs of pemphigus rise abruptly from the sound skin; have no inflammatory areola, and are, in most cases, tensely filled with a clear, yellowish—sometimes purulent—fluid, or at times containing blood.

In a few days, the fluid is reabsorbed; the roof of the bleb, with some of its contents, dries into a thin scale, which, when removed, leaves a reddened, but otherwise apparently healthy base. If, by means of the prick of a needle, or otherwise, the contents of the bleb are discharged, the latter collapses, and dries up, as in the last instance. Unless irritated by mechanical means or stimulating applications, pemphigus blebs rarely contain pus, and no ulceration takes place at their base; hence uncomplicated pemphigus leaves no scars. The blebs consist of single cavities, not subdivided into compartments, as are the pustules and bullæ of smallpox in their earlier stages.

The disease probably most frequently mistaken for pemphigus is impetigo contagiosa. This appears in the form of pea to chestnut-sized blebs, rising abruptly from a non-inflammatory base, but usually flaccid, not tensely filled with fluid like those of pemphigus. The borders of the blebs of impetigo contagiosa are also usually more irregular—not so perfectly rounded or oval as those of pemphigus. They contain a clear fluid, which rapidly becomes changed into a thin, milky pus. The fluid is soon absorbed, or dries with the roof of the bleb into a thin brownish crust with turned-up border lightly adherent at the centre, as if "stuck on" as Tilbury Fox described it. Impetigo contagiosa usually first appears on the face, and, being auto-inoculable, may be transferred to other portions of the body. It is very contagious and usually affects all the children of the same family. In most cases it runs its course in two to four weeks, and hence, probably originate the accounts of epidemics of acute pemphigus, which we so often see in the journals. The resemblance is often very close between the two diseases, and only a careful investigation will disclose the true nature of the disease in many instances. If the characteristic marks of the two diseases are remembered, however, no mistake should occur.

In a number of cases of erysipelas, frost-bite, burns and scalds, the application of cantharides or mezereon, bullæ appear on the affected part. Here pemphigus can always be excluded by the presence of the uniformly reddened or inflamed base upon which the blebs appear.

In the later stages of acquired syphilis a bullous eruption sometimes appears, which is termed by some authors, "syphilitic pemphigus." The name is misleading, as the eruption of bullæ is the sole point of resemblance. The bullous syphiloderm, as this affection is more properly termed, is differentiated from pemphigus, by an inflammatory areola surrounding the base of the bleb, which becomes purulent, the contents drying into a greenish-brown scab seated upon an ulcerated base, constituting what is called rupia. The bullous syphiloderm is more frequent in children as a manifestation of inherited syphilis.

The early stage of true leprosy is frequently accompanied by an eruption of bullæ. In this disease, however, some hyperæsthesia, followed by anæsthesia of the spots occupied by the blebs generally precedes the eruption. Other concomitant symptoms of grave involvement of the constitution will also be present, and enable the physician to exclude pemphigus.

Smallpox, as the cases before related go to show, may cause a difficulty in diagnosis—a difficulty which is perhaps more serious than that presented by most other diseases, on account of the results which may ensue if a case of the latter should fail to be recognized. In smallpox, however, the blebs always contain pus or blood; are not simple cavities, but subdivided into compartments; are seated upon an inflamed base, and followed by ulceration and loss of substance. The prodromic symptoms of smallpox can also usually be verified in the latter disease; these do not occur in pemphigus.

In rare cases of exudative erythema, large blebs sometimes occur as one of the multiform manifestations of this disease. The accompanying papules and the generally present patches of diffused red or brownish discoloration will serve to distinguish the affection. Dr. I. E. Atkinson has described some interesting examples of the bullous form of erythema multiforme in The Medical News for December 2, 1882. The so-called herpes iris, which has doubtless sometimes been mistaken for pemphigus, is now generally regarded as merely one of the forms of exudative erythema.

In some rare cases of urticaria, the summit of the wheal is occupied by a bleb, which may simulate the bullous eruption of pemphigus. The presence of other wheals, the urticarial irritability of the skin, and the intense itching in urticaria will serve to distinguish it from pemphigus.

Charcot has pointed out that a bullous eruption sometimes occurs in consequence of nerve-lesions. These eruptions may appear consecutively, simulating the recurrent eruptions in pemphigus. Scars remain in these cases, however, to mark the seat of the blebs, which is an exceedingly rare result in pemphigus. In the latter disease, also, the eruption would not be so strictly limited to the area supplied by an injured nerve.

Scabies is occasionally accompanied by large bullæ. The presence of papules, pustules, furrows, and excoriations, accompanied by severe itching, and the acarus, discoverable with a lens, would exclude pemphigus.

In ecthyma, large pustules are formed, which may be mistaken for the bullæ of pemphigus. The free pus production, the inflammatory areola around the base of the blebs, and the resulting greenish crusts and superficial ulceration in ecthyma render the diagnosis easy.

An important, possibly frequent, and certainly rarely recognized cause of bullous eruptions is the ingestion of certain medicines. Arsenic, potassium bromide and iodide, quinia, copaiba, and phosphoric acid, have been followed by bullous eruptions, more or less resembling pemphigus. It should in all cases of doubt be ascertained whether such medicines have been taken before deciding upon the diagnosis.

It needs to be added that the practitioner must be constantly on his guard against being victimized by feigned bullous eruptions, *i. e.*, eruptions of blebs caused by the designed application of chemical or dynamical irritants to portions of the skin with intent to deceive. Hysterical women are, of course, the most frequent offenders in this respect, but it must not be forgotten that men sometimes maling by feigning various formidable skin eruptions. The methods by which bullæ are produced artificially consist in the hot iron, sinapisms, cantharides, strong acids or alkalies, and perhaps in some instances, prolonged pressure. The possibility of this occurring must be constantly borne in mind in order to avoid being discomfited by a malicious or dishonest patient.

While it may be necessary in some cases to defer giving a positive diagnosis for one or several days, close observation, and recollection of the points of distinction here laid down will nearly always enable the practitioner to differentiate between pemphigus and other bullous eruptions.

AN EXTREMELY COMPLICATED CASE OF CICATRICIAL CONTRACTION FROM BURNS.

BY ALFRED C. POST, M.D.,

CONSULTING SURGEON TO THE NEW YORK, ST. LUKE'S, AND WOMAN'S HOSPITALS; VISITING SURGEON TO THE PRESBYTERIAN HOSPITAL, NEW YORK.

(*Read before the New York Surgical Society, May 22, 1883.*)

MRS. I. L., widow, aged thirty-two years, admitted into Presbyterian Hospital, August 8, 1882.

On the 6th of June, 1881, she was severely burned on her face, hands, and forearms, by an explosion of gunpowder. Two months elapsed after the injury before the burned surfaces had healed. Hard cicatricial bands were left upon the lower part of the face, extending from the chin to the ears, more extensive on the left than on the right side. The lobe of the left ear was completely enveloped in cicatricial tissue, a portion of its surface being exposed at the bottom of a deep pocket. The hands were greatly disfigured, and were scarcely of any use to the patient.

Right hand: The ring and little fingers were flexed at the metacarpo-phalangeal articulations, and at the articulations between the first and second phalanges. The little finger was thrown in advance of the ring finger, and any attempt to straighten it was resisted by a firm cicatricial band, extending from the ulnar margin of the finger towards the pisiform bone. The point of the little finger was separated from the palm of the hand only to the extent of two centimetres. The ring finger was also fixed in a flexed position by a very firm cicatricial band on its ulnar margin, binding it to the ulnar margin of the hand, and resisting any effort to extend it beyond an angle of 120°. The index and middle fingers were nearly normal. The first phalanx of the thumb was bent forward at an obtuse angle upon the metacarpal bone, fixed by a cicatricial band passing from the radial margin to the wrist. The last phalanx was bent backward at an angle of 110°. The dorsal surface of the thumb was covered with cicatricial tissue, offering considerable resistance to efforts which were made to straighten the member at the articulation between the first and second phalanges. The integument of the forearm was covered around its whole circumference by moderately firm cicatricial tissue, extending on the ulnar side to the vicinity of the elbow. The dorsal surfaces of all the fingers were webbed together, the surfaces between the index and middle, and middle and ring fingers as low down as the anterior edge of the commissures, and the space between the ring and little finger, nearly as low as the articulation between the first and second phalanges.

Left hand: Index and middle fingers are bent backward at articulation between first and second phalanges, and firmly held in that position by strong bands of cicatricial tissue. The ring finger is flexed, almost at a right angle, at the articulation between the first and second phalanges, and fixed in that position by two nearly parallel bands of considerable thickness. The little finger is flexed at an angle of 75° at the articulation between the first and second phalanges, and is firmly fixed by a dense mass of cicatricial tissue, which occupies the whole space of the integument between the first and second phalanges, binding the whole of the middle phalanx to the palm of the hand. The first phalanx is bent far backward. The whole integument of the hand presents a cicatricial character. This condition extends upon the forearm, three or four centimetres above the wrist. The thumb presents a condition almost identical with that of the right hand. Masses of cicatricial tissue extend across the dorsal surfaces of the commissures of all the fingers, webbing them together more than half way to the articulations between the first and second phalanges.

First operation, August 10th; right hand: Multiple division was made of the cicatricial bands which fixed the ring and little fingers in a flexed position, and which contracted the palm of the hand. The fingers could then be extended, and the tension of the palm relieved. The wounds were washed with carbolic acid, 1 to 20, and dressed with lint saturated with carbolic oil, two scruples of carbolic acid to one drachm of olive oil. A dorsal felt splint, with digital prolongations, was applied, fortified with strings of hoop iron, one for each finger, the splints extending up nearly to the elbow. Each finger was fixed in an extended position to the corresponding portion of the splint with narrow strips of adhesive plaster. Wider strips of adhesive plaster secured the splints to the forearm, and a gauze bandage was applied over the whole.

Left hand: An operation was performed similar to that on the right hand, except that the distal extremity of the proximal phalanx of the little finger was excised with bone forceps, after having been exposed by a longitudinal incision dividing the skin, the aponeurosis of the extensor tendon, and the periosteum. The dressings were the same as on the other hand.

Aug. 15.—The dressings were removed for the first time since the day of the operation. The wounds were washed with carbolic acid, 1 to 40,

and dressed as before, they were beginning to granulate and were free from inflammation.

18th.—Dressed as before; the wounds were in good condition.

25th.—The wounds have been dressed every other day, and passive motion applied to the fingers. The wounds are nearly healed.

Sept. 11.—The wounds are healed. The splints were left off from the right hand, and from the ring finger of the left hand to allow passive motion of the fingers.

12th.—Reapplied splints.

16th.—Left off splints again for twenty-four hours.

17th.—As the fingers showed a strong tendency to recontraction, the splints were again applied.

27th—The splints removed at 6 A.M., and reapplied at 11.30 A.M.

Oct. 4.—Second operation: This was performed to improve the position of the thumbs. Right thumb: A longitudinal incision was made over the dorsal surface of the distal articulation of the thumb, exposing the bone. The distal end of the proximal phalanx was then excised with cutting forceps. Five transverse incisions were made across the longitudinal ones, but not deeper than the cicatricial tissue. A similar operation was performed on the left thumb. The wounds were dressed in the same manner as after the first operation. The thumbs were brought into a slightly bent position, and secured in that position by dorsal splints of hoop iron.

10th.—Removed the dressings.

25th.—Since last date the dressings have been removed and passive motion employed every other day. The wounds are nearly healed.

Nov. 1.—The distal phalanges of the thumbs are nearly in their normal position, but with some tendency to backward flexion. The metacarpal bones of the thumbs are adducted by strong cicatricial bands on their palmar and dorsal surfaces. The index, middle, and ring fingers of the right hand are nearly normal in position and mobility, while the little finger is maintained in a state of partial flexion and slight adduction by a dense cicatricial band which extends along the palmar surface and ulnar edge nearly up to the wrist.

The ring and little fingers of the left hand are still somewhat flexed at the articulations between the first and the second phalanges, while there is some backward flexion of their metacarpo-phalangeal articulations.

Third operation: The cicatricial integuments on the dorsal surfaces of both thumbs were freely divided by a series of oblique incisions intersecting each other at right angles, so as to divide the aforesaid cicatricial integuments into a series of parallelograms, about seven millimetres in diameter. On the left hand, the cicatricial tissues were also divided on their palmar surface by a series of parallel incisions extending over the radial margin of the thumb. The cicatricial webs uniting the several fingers of the left hand on their dorsal aspect were divided by the longitudinal incision in each interdigital space, and by a number of parallel transverse incisions on t e lateral surface of each finger.

On the right hand, similar longitudinal incisions were made through the webs on the dorsal surfaces of the fingers, and nearly parallel with the longitudinal incision on the dorsal surface of the web connecting the dorsal surfaces of the index and middle fingers, a V-shaped incision was made, so as to liberate a triangular flap whose apex pointed upward about three centimetres above the commissure, the base of said flap including the main longitudinal incision at the commissure. On the outer surface of the integument, covering the first phalanx of the little finger and its metacarpal bone, twelve transverse incisions were made through the contracted cicatricial tissue which drew the fingers in the direction of adduction and posterior flexion. The usual dressings were applied, but the application of splints was postponed until the next day.

22d.—The dressings were renewed, and splints applied to draw the several parts in a direction opposed to the deformity. After the first few days, the dressings and splints were removed every other day, and passive motion employed at each dressing.

Dec. 5.—Fourth operation: right hand. The principal remaining deformities to be overcome were undue approximation of the metacarpal bone of the thumb to that of the index finger, and abnormal flexion of the little finger. To overcome these deformities, free multiple incisions were made through the cicatricial bands occupying the commissure between the thumb and the index finger, and also through the dense band on the palmar surface and ulnar edge of the integument covering the little finger and its metacarpal bone. The thumb and index finger were then widely separated from each other, and secured by splints of hoop iron, one on the radial side of the thumb, and the other on the dorsal surface of the index finger. The little finger was brought into a state of exaggerated extension, and fixed in that position by a band of iron on the dorsal surface. All these splints extended above the middle of the forearm.

Left hand: the deformities to be overcome were, as far as concerned the commissure between the thumb and the index finger, the same as on the right side, and a similar operation was performed. The remaining deformity on this side was chiefly a flexed condition of the ring finger, involving the articulations between the first and second, and second and third phalanges. This flexion was maintained by a very firm cicatricial band, occupying the whole breadth of the palmar surface of the finger. I divided this band by a number of parallel oblique incisions, downward and outward, intersected by other parallel incisions downward and inward. The finger was then brought into a state of exaggerated extension, and secured by an iron band on its dorsal surface.

10th.—The wounds have been dressed every other day; they were in a very good condition.

25th.—The wounds are nearly healed; the parts are maintained in good position.

Jan. 11, 1883.—Fifth operation. This was performed to relieve the backward traction of the thumbs at their distal articulations. It was similar

to the operation performed on the 4th October. It consisted in the exsection of the distal extremities of the second phalanges, which were exposed by means of free longitudinal incisions on their dorsal surfaces, in addition to the longitudinal incision required for the exsection of the extremities of the phalanges. Multiple transverse incisions were made through the cicatricial tissue on each side, the usual dressings were applied to the wound, and the terminal phalanges of the thumbs were fixed in a flexed position by the application of bandages around them and the hands.

Feb. 14.—Sixth operation. The little finger of the right hand, and the ring and little fingers of the left hand being flexed at angles of about 135°, multiple incisions were made across their plantar surfaces, the fingers were brought into a state of exaggerated extension, and fixed by means of splints to their dorsal surfaces.

March 26.—Seventh operation. The right little finger, and the left ring and little fingers remaining still abnormally flexed, the operation of Feb. 4th was repeated upon them, and they were again fixed by appropriate splints in a position of exaggerated extension. The left index and middle fingers being bent backward at the articulation between the first and second phalanges by broad cicatricial bands on their dorsal surfaces, multiple oblique incisions were made downwards and inwards, and downwards and outwards, dividing the bands into rhomboidal segments; these fingers were then bent forwards, and secured in a flexed position by splints applied along their palmar surfaces.

April 12.—Eighth operation. The lobe of the left ear being enveloped in a mass of cicatricial tissue, I made a curved incision around its lower extremity and liberated it from its abnormal attachments, and then by excising a small portion of the subcutaneous tissue, was able to reunite the integument over its margin, and to secure it by fine sutures. I also brought together and secured by sutures the edges of the wound upon the side of the neck from which the lobe had been liberated.

20th.—I removed the last of the sutures to-day. The margin of the lobe has healed, and the insulation of the lobe from the parts with which it had been incorporated is completely established.

26th.—Ninth operation. This was performed for the purpose of improving the position and increasing the mobility of the right little finger, which was still somewhat flexed, and considerably adducted, and whose replacement in its normal position was resisted by a very dense cicatricial band along the palmar surface and the ulnar margin of the little finger and of the hand. This band had been repeatedly divided, and the parts had been stretched, but in consequence of the difficulty of applying force advantageously to overcome the adduction, not as much relaxation of the contracted tissue had been obtained as seemed desirable. On the present occasion I made numerous oblique incisions, dividing the cicatricial tissue into small rhomboidal segments, and brought the finger into a state of nearly perfect extension: I also overcame the adduction. But after making as thorough a division of the cicatricial band as seemed to be advisable, it required some force in the way of traction to maintain the improved position of the finger. I washed the wounds with carbolic acid, one to twenty, and enveloped the finger in sheet lint moistened with carbolized oil. To maintain the improved position of the finger, I resorted to the following method: I first applied an iron splint along the radial side of the index finger and of the forearm, the digital extremity of the splint being bent at an obtuse angle, so as to bring the finger into a state of forced abduction. The middle finger was then secured to the index by a broad strip of adhesive plaster, and in like manner the ring finger was secured to the index and middle fingers. The little finger was then brought into an extended position, and secured by a dorsal splint, and the adduction was overcome by drawing it firmly out and binding it to the other fingers by a broad strip of adhesive plaster. A gauze bandage was then firmly applied around the hand and forearm. The fixation of the index, middle, and ring fingers in a position of abduction seemed to be indispensable as a means of overcoming the obstinate adduction of the little finger. It was an evil, but it appeared to me to be an unavoidable one.

May 22.—The treatment last described was continued with some modifications until the 17th instant, when the iron splints were discontinued and wooden splints were applied to the dorsal surfaces of the forearms and hands, secured by roller bandages. This change was made as a matter of convenience, the fingers having been brought nearly into their normal position, and but little active force being required to keep them in place.

The treatment of this obstinate case has been brought nearly to a close. The hands will require the support of bandages and splints for some time to come, and the persevering use of passive motion will be required to restore mobility to the fingers. The result of the treatment is not perfect, but considering the difficulties of the case it has been as satisfactory as might reasonably have been expected.

In reviewing this case it will be observed that the deformities of the thumbs and fingers produced by the cicatricial contractions were of a very complicated character, owing to the fact that the hands had been severely burned both on their palmar and dorsal surfaces, and that the proximal and distal phalanges of the same member had been drawn in the opposite direction of flexion and extension. In consequence of these complications it was a very difficult matter to apply force in such a manner as to overcome deformity in one direction without increasing it in another.

In the course of the treatment it became necessary in several instances to repeat the operation upon the same parts which had already been operated on, as the tissues which had been divided had reunited so as still to offer strong resistance to forces tending to overcome the deformity, and in each instance some benefit was derived from the repeated division of the cicatricial bands. If the deformity had been only in the direction of flexion, or only of extension, the problem would have been much

simpler, and better results could have been obtained in a much shorter time.

Each operation was performed while the patient was under the anæsthetic influence of ether, and the repeated etherizations were well borne by the patient. No considerable amount of inflammation followed any of the operations. There was no sloughing at any time of even the most minute portion of the divided tissues, although, in a number of instances, cicatricial bands were divided into small segments. The divided parts began to assume a healing character within a very few days after each operation, and, in most instances, the healing process was complete within two or three days.

After each removal of the splints, before reapplying them, passive motion was freely employed: this often occasioned a considerable degree of pain, which, however, soon subsided after the reapplication of the splints.

Occasionally, when one or more of the fingers had been kept for many days forcibly stretched in a direction opposite to that of the original deformity, it seemed disposed to become rigidly fixed in the position in which it had been held. In such cases, the splints were left off for a day or two, with directions to make free use of passive motion; but very soon there was a tendency to a return of the old deformity, and it became necessary to reapply the splints, and, in some instances, to redivide the cicatricial bands. These changes in the details of the treatment seemed to be necessary to prevent rigidity, and to overcome deformity. The treatment of a complicated case of cicatricial contractions, like the one which has been described, must necessarily be extended over a long time. The contracted parts must be very freely divided at many points through the whole thickness of the cicatricial tissue, and the parts must then be stretched, as far as possible, in a direction opposite to that of the deformity, and maintained in that position during the healing of the wounds and for a long time afterwards. By perseverance in this course for a sufficiently long period, paying constant attention to the most minute details of the treatment, the case may be conducted to a successful issue; and if the patient be careful to practise active and passive movements of the affected parts to a sufficient degree, the tendency to a recurrence of the deformity and of the rigidity of the parts will be finally overcome.

MEDICAL PROGRESS.

Cystotomy by a Modified Lateral Method.—Mr. Reginald Harrison has had cases in which, on account of an enlarged prostate, it was necessary to make an opening into the bladder from the perineum, the usual means of relieving obstructed micturition, or its consequences, having failed. He reports the details of such a case—a man, æt. 63, who had been suffering from frequent micturition, caused by an enlarging prostate. Finally, the irritability increased so much that it was sometimes difficult for him to hold his urine for more than ten minutes, and Mr. Harrison determined to open the bladder. The patient being placed under ether in the lithotomy position, a small grooved staff was introduced into the bladder, and a limited incision made down upon it laterally, opening the urethra in the membranous portion. The staff being necessarily a small one, he was enabled to pass his right index finger into the bladder without removing it. On doing so, he found that, though the prostate was not very large, the orifice of the bladder was obstructed by one of those nipple-like enlargements of the third lobe, which are sometimes more effectual in rendering micturition difficult and catheterism uncertain, than more general hypertrophies.

Finding that he could obtain his object and free the neck of the bladder without attempting to remove or enucleate any portion of the gland, he did not carry the incision into the bladder along the groove of the staff, but introduced on his forefinger (having now removed the staff), a straight, narrow, probe-pointed bistoury, by which he divided what seemed to be the obstructing portion of the prostate. The finger then entered the bladder easily, whereas previously it was with the sensation that a source of obstruction existed, which was quite capable of rendering catheterism difficult. On again using the knife for the purpose of slightly enlarging the superficial incision to avoid bagging, the rectum, which had been accustomed to prolapse very much, suddenly filled the wound, and came into contact with the knife; a small puncture of the bowel was the result. He is disposed to think, however, that it proved a not unimportant feature in the case.

A lithotomy-tube was introduced, to which rubber tubing was attached for draining and keeping the patient dry. The operation was followed by a rapid cessation of the hemorrhage and a decline of the cystitis. On the third day after, it was reported, "Patient in good condition; sleeps and eats well; pulse 80; temperature has never exceeded 100° Fahr." On March 15, the report states, "Wound looks healthy; appears to be closing up; passes his urine mainly through it: some by the urethra." At times, a little feces made its way into the wound, escaping through the perineum. The amount was so small as not to occasion any inconvenience, whilst it proved to be an obstacle to the speedy closure of the incision into the bladder. Within eight weeks from the time of operation, the patient was able to leave the infirmary.—*British Med. Journal*, June 9, 1883.

Bismuth in the Treatment of Ulcers.—Dr. Truckenbrod has treated, at the Würtzburg Polyclinic, cases of varicose ulcers and others, of the legs, with subnitrate of bismuth sprinkled on the ulcer until a thin layer was formed, when a bandage was applied. In the cases of varicose veins, a rubber bandage was employed. The ulcers were healed, generally, in a few days. This treatment seemed to give better results than the use of iodoform.—*Centralbl. für klin. Med.*, March 24, 1883.

Disappearance of a Tumor under the influence of Erysipelas.—Dr. T. Stein (*Vratch*, No. 16, 1882) describes a striking instance of "*erysipèle salutaire*" (Champouillon). A sickly peasant woman, aged 48, complained of a pain and tumor in her right breast, which had appeared about a year previously. The mammary gland was found irregularly enlarged, fixed to the chest-wall, hard, knobbed, at some points fluctuating; the skin was adherent, showing dilated veins. The age of the patient, the moderate rate of the growth of the neoplasm, the hardness and immobility of the tumor, and the cachexia pointed to a malignant disease (cancer or sarcoma). The author persuaded his patient to undergo operative treatment; and meanwhile, keeping in view her anæmic state, he made an

injection (half of a Pravaz's syringe) of pyrophosphate of iron with citrate of soda in the dorsal region. About twelve hours later, severe erysipelas of the neck and chest (and afterward of the head) appeared, starting from the spot of the injection. The attack kept the patient in bed twelve days. On examination on the thirteenth day the author, to his utter astonishment, found no tumor; nothing but two indurated knots, each of the size of a small walnut, remained. At the same time a great improvement of her general health followed. Dr. Stein was able to find out in literature only very few similar cases.—*London Medical Record*, May, 1883.

EFFECTS OF MEDICINAL SUBSTANCES ON MILK SECRETION.—DR. STRAUPF, after numerous investigations, comes to the following conclusions on this subject: First, as to the quantity of the milk—1. A considerable diminution takes place under the use of iodide of potassium. 2. No change is produced by alcohol, morphia, or lead. 3. A slight increase takes place from salicylic acid. 4. There is, perhaps, a diminution from pilocarpin. 5. A considerable diminution, and sometimes a total suppression, is produced by ergotin. Next, as to the quality of the milk—1. The iodide of potassium so disturbs the secretion of the mammary glands that it is impossible to recognize the modifications which the milk undergoes. 2. Alcohol, and in general all the drinks which contain it, increase the proportions of the fatty elements. 3. Pilocarpin, morphia, and lead produce no change. 4. Salicylic acid increases the proportion of sugar of milk. 5. No particular form of diet is capable of increasing the secretion of milk.—*Medical Times and Gazette*, May 26, 1883.

LOCAL ANÆSTHESIA.—M. VIDAL has observed that local anæsthesia by the ether spray is hastened by applying a thin layer of wadding to the skin, and directing the spray upon that. If the skin is punctured after refrigeration, the local congestion seems to prevent a second refrigeration.—*Gaz. Hebdom.*, May 25, 1883.

CANNABIS INDICA IN MENORRHAGIA.—MR. JOHN BROWN, in a communication to the *British Medical Journal*, May 26, 1883, says, with regard to the use of cannabis indica in menorrhagia, that his experience confirms, in some respects, Mr. Oliver's views, especially regarding its physiological action. In no case has it induced pleasurable feelings, generally most alarming symptoms, such as complete paralysis, horrible hallucinations, double consciousness, etc. A young practitioner should be most careful in prescribing, and warn patients of its action, or he may lose their confidence. Indian hemp has been vaunted as an anodyne and hypnotic, having the good qualities of opium without its evils. Also in dysmenorrhœa. In this complaint and insomnia it has not proved of much benefit. The drug has almost invariably produced some marked physiological effect even in small doses. Text-books give the dose as ten minims and upwards, but five minims is the largest dose that should be given at first. If bought from a good house, the drug is not inert or unreliable. A drug having such marked physiological action ought to have a specific use as a therapeutic agent. Indian hemp has such specific use in menorrhagia—there is no medicine which has given such good results; for this reason, it ought to take the first place as a remedy in menorrhagia, then bromide of potassium and other drugs. The *modus operandi* I cannot explain, unless it be that it diverts a larger proportion of blood to the brain, and lessens the muscular force of the heart. A few doses are sufficient; the following is the prescription: ℞. Tincturæ cannabis indicæ, ♏ xxx; pulveris tragac. co. ʒj; spiritus chlorof. ʒj; aquam ad ʒij. One ounce every three hours. Four years ago I was called to see Mrs. W., aged 40, multipara. She had suffered from menorrhagia for several months. Her medical attendant had tried the ordinary remedies without success. Indian hemp was given as above. Its action was speedy and certain. Only one bottle was taken. She was afterward treated for anæmia, due to loss of blood. Twelve months after this my patient sent for a bottle of the "green medicine." I learnt afterwards that she had sent this medicine to a lady friend, who had been unsuccessfully treated by another medical man for several months for the same complaint. It proved equally successful. The failures are so few, that I venture to call it a specific in menorrhagia. The drug deserves a trial. It may occasionally fail; this, however, is not to be wondered at in a complaint due to so many different causes, and associated with anæmia and other cases of plethora.

DR. ROBERT BATHO, in a note to the same journal, confirms the statements of Mr. Brown regarding its value in menorrhagia.

BULBAR LESIONS IN ATAXIA.—MM. LANDOUZY and DEJOSINE have recently made some very interesting studies as to the bulbar lesions in ataxias presenting laryngeal crises. They have found posterior sclerosis extending to the beak of the calamus scriptorius; the bulbar roots of the spinal and pneumogastric nerves presenting gross lesions precisely similar to those of the posterior roots of the cords. In the medulla, the decussating fibres and the origins of the pneumogastric and spinal nerves were profoundly altered on both sides. These lesions are sufficient to explain the laryngeal crises, but the intermittence of the crises is still unexplained.—*Gaz. Hebdom.*, May 25, 1883.

ASPIDIUM MARGINALE, A NEW TÆNIFUGE.—DR. CRESSLER has obtained excellent results from the use of the oleo-resin of *Aspidium marginale* as a tænifuge. The oleo-resin is put in capsules of about grs. x each, and administered after a total abstinence of twelve hours from food. A dose of castor oil is administered about one or two hours afterward. The *Aspidium marginale* is related to the male fern.—*União Medica*, April, 1883.

PROLONGED BATHS IN VIOLENT MANIA.—J. MILLET, in concluding an article on this subject, says that prolonged baths of a temperature of 77°–93° Fahr., are a most useful and efficacious means for combating the violent paroxysms of mania in the insane; their constant effect is to moderate the violence, lower the temperature, and diminish the frequency of the pulse. These results are more manifest and persistent as the baths are given at the lower temperature and for a more protracted period. The more violent the paroxysms, the colder and more prolonged should the bath be. Feebleness of constitution, emaciation, malnutrition, and the existence of fever are indications for a higher temperature and less duration of the bath. Baths of two to five hours, and at a temperature of 77° to 82° Fahr., should be administered to violent patients. If the bath is more prolonged, the temperature should be from 82° to 88°, especially if the agitation is not excessive. Baths of 88° to 93° should be reserved for cases in which there is moderate excitement in an emaciated, puny subject, or one enfeebled by fever or malnutrition. During the baths the head should be covered by cold compresses, frequently renewed, in order to prevent cerebral congestion, or else keep a current of cold water playing on the head. Baths of 96° Fahr., may

be said to be neutral; while they modify the temperature and the pulse, they ordinarily increase the agitation of the patients. Baths of and above 98° Fahr. elevate the temperature, accelerate the pulse and respiration, and when prolonged debilitate the organism and are followed by fatigue. They are rarely indicated.—*L'Encéphale*, No. 3, 1883.

THE UTERUS IN PUERPERAL ECLAMPSIA.—DR. BRAXTON HICKS read a paper on this subject before the Obstetrical Society of London, on May 2, and described two cases in which he had made careful observations. In each of them, coincidently with a convulsion, a powerful and prolonged contraction of the uterus was observed. Between the convulsions, the uterine action was natural. He could not state the exact relationship in point of time between the convulsions and uterine contraction. He did not think that uterine contraction alone caused the convulsion; for in the most severe cases of tonic or clonic contraction of the uterus, convulsions did not occur. But there might in these cases be increased excitability. It had been suggested that increased force of pains might result from carbonic acid intoxication due to the convulsions. He thought the immediate supervention of uterine contraction in the convulsive paroxysms and the quietness of uterine action between them told against this view. The presence of these contractions, together with the disturbance of the heart and vascular system, and the pupil, showed that the muscles of organic life were liberally affected during the paroxysms of eclampsia. These prolonged and powerful uterine contractions, as well as the carbonic acid poisoning of the mother's blood, were a source of danger to the fœtus, and in its interest speedy delivery was called for, if it could be effected without harm to the mother.

DR. ROBERT BARNES thought that with chloroform and improved operative measures delivery might be effected early and safely; but the mother must be considered first.

DR. GRAILY HEWITT thought the disturbances of the abdominal and renal circulation, caused by pressure of the gravid uterus on the renal veins, exercised a powerful influence in producing eclampsia. He had found benefit from diminishing this pressure by positional treatment, and by unloading the bowels.

DR. ROUTH had seen marvellous benefit in puerperal convulsions from placing the patient on her belly and knees, a confirmation of Dr. Hewitt's views.

DR. HICKS did not recommend force in the delivery of the child. As to the effect of pressure, there was often no albumen in the urine before the first convulsive seizure.—*Lancet*, May 26, 1883.

THE MOTOR CENTRE OF THE LOWER LIMBS.—Ferrier gives the motor centre of the lower limbs as the upper part of the ascending parietal convolution and the adjacent portion of the ascending frontal. MM. HALLOPEAU and GIRAUDEAU, after an extended study of the literature of the subject, together with the details of an interesting case, conclude that Ferrier is correct. Of fourteen cases, the upper part of the superior parietal convolution was involved, either alone or with the adjacent convolution, in *eight* cases; the paracentral lobule was involved *seven* times; the upper part of the ascending frontal was involved *six* times, and the superior parietal lobule *twice*. From these facts they conclude: 1. That there exists in man a distinct territory of the cerebral cortex, which presides over the movements of the lower limbs. 2. That the centre of this territory is the upper third of the ascending parietal lobule and the paracentral lobule, encroaching in front upon the upper part of the ascending frontal, behind on the superior parietal lobule.—*L'Encéphale*, 3, 1883.

STIGMATA OF MAIZE AS A DIURETIC.—DR. VIDAL SOLARES asserts that the stigmata of maize is an efficient diuretic, producing no unpleasant nervous or digestive disturbances, is well tolerated by the stomach, and may be used for a long time without producing any unpleasant effects. It regulates the pulse, augments the arterial tension and diminishes tension in the venous system.—*União Medica*, April, 1883.

RADICAL CURE OF HERNIA BY DISSECTION.—At the last meeting of the surgical section of the Academy of Medicine, MR. WILLIAM STOKES exhibited a patient whom he had operated on by this method for a strangulated inguinal hernia of the left side. The other side had been operated on in Liverpool some time since by the ordinary method, and had failed. Mr. Stokes dissected down to the pillars of the ring and stitched them and the perineum together with a piece of catgut. The operation was performed five months ago, and has turned out most successful. Mr. H. Gray Croly exhibited also on the same occasion a patient with inguinal hernia, in which the same method was used with a similar result.—*Lancet*, May 26, 1883.

ASTHMA AND NASAL POLYPI.—DR. JOAL, in a pamphlet on this subject, based on ten observations, shows that nasal polypi may be accompanied by suffocative feelings, and may often cause attacks of asthma, as these oppressive symptoms disappear when the tumors are removed. The author draws the following conclusions: 1. Mucous polypi of the nose sometimes occasion dyspnœic troubles of asthmatic nature, but they may be totally without influence on the production and progress of these troubles, or may be a simple coincidence. 2. This symptomatic asthma is observed principally in arthritic subjects, and in aged persons. 3. It is more often produced by reflex action following irritation of the nasal mucous membrane, produced by polypi. 4. The point of departure of the excitation may be the sensitive filaments of the pneumogastric supplying the pharyngeal or bronchial mucous membrane, which are influenced in the modified respiratory act by obstruction of the nasal passages. 5. Asthma may be due to catarrhal and emphysematous lesions attributable to nasal polypi. 6. The asthmatic accidents improve or disappear after ablation of the polypi. 7. The nervous troubles produced by polypoid tumors of the nose, may be confined to periods of spasmodic sneezing.—*Revue Méd. Franc. et Étrang.*, May 26, 1883.

HYDATID CYST OF THE BICEPS.—Hydatid cysts of the biceps are very rare, three cases having been reported by Blandin, Saele, and Dupuytren. MR. PICQUÉ now publishes a fourth. In September, 1882, a woman came under the care of M. Gosselin, with a large tumor situated on the anterior part of the left arm. The tumor first appeared two years ago, was for a long time very small, and gave rise to no pain. In July, 1882, it very suddenly became much larger, and soon attained the size of a child's head. It was elastic, fluctuating, movable over the deeper structures, was very regular, and occasioned no alteration of the skin; the humerus was sound, the beats of the radial artery were normal, and sensibility was only slightly influenced. There was nothing about the tumor indicative of aneurism. The axillary glands were not at all enlarged, and a malignant growth was thrown out of the diagnosis. The cyst was punctured and found to be a suppurating hydatid cyst; it was opened, the contents turned out, and the wound dressed. Recovery took place without accident, and without impairment of the functions of the arm.—*Gaz. Méd. de Paris*, No. 12, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, JUNE 23, 1883.

THE JOHNS HOPKINS UNIVERSITY.

IN the course of some remarks made by President Gilman of the Johns Hopkins University, on the occasion of conferring degrees upon its graduates at the close of the academic year, June 7th, he referred to the fact that the Johns Hopkins Hospital is approaching completion, and that the organization of the medical department of the University must soon be taken in hand. As a preliminary step to this end, and in order to secure uniformity of plan and harmonious relations between the University and the Hospital, the trustees have designated as Professors in the Medical Department, Drs. Remsen, Martin, and Billings, for the Chairs of Chemistry, Physiology, and Hygiene, respectively.

Drs. Remsen and Martin are already professors in the University, the former of chemistry, and the latter of biology, and each of these has recently been provided with a large and well-appointed building, containing laboratories, lecture-rooms, etc.

It is not probable, as we learn, that Dr. Billings can accept the full title and responsibilities of a professorship, since he is unwilling to give up his library work, at present, at all events, but he may deliver a short course of lectures upon some subject or subjects connected with sanitary science, and will coöperate and advise in regard to the organization of the medical school.

It is understood that other professors will soon be appointed, and in particular, that the Chair of Pathology will soon be established.

Of course, nothing has yet been determined as to the character of the medical instruction which is to be given, the preliminary education to be required, or the conditions upon which the University is to grant the degree of Doctor of Medicine, but we can form some idea of what the conclusions ought to be upon these various points if the medical department is to be established and maintained upon the same general grade as that adopted for other departments of the University. An examination of the new schedule of studies recently issued for the collegiate department of the University, shows that if a young man wishes to obtain the degree of Bachelor of Arts in the course of study which is arranged with special reference to the needs of those who intend to study medicine, he must possess the following qualifications:

The requirements for his matriculation are a knowledge of Latin (Cæsar, Ovid, Virgil, and Cicero); Greek (Xenophon, Herodotus, Homer); mathematics (arithmetic, algebra, geometry, plane and solid, plane trigonometry and analytic geometry); the outlines of the history of England and the United States; English grammar, analysis, and composition; and either the elements of physics, of chemistry, of botany, of physiology, or of physical geography, as he may elect. French and German may be offered instead of Greek.

Students who wish to enter upon the biological courses preliminary to medicine without reference to the degree of B.A., will be examined at entrance in the following subjects:

Mathematics: Arithmetic, algebra (simple equations involving not more than two unknown quantities), three books of Euclid, plane trigonometry, and the use of logarithms. Latin: First four books of Cæsar, and sixth book of the Æneid. English: Lounsbury's History of the English Language, written composition, physical geography.

The young man who has matriculated with the view of taking the degree of B.A., and then of studying medicine, is to pursue the following studies, or at all events, to pass satisfactory examinations in them, viz.: English composition and literature, German and French, logic, ethics and psychology, physical geography and ancient history, drawing, vocal culture, physical culture, theory of accounts, and daily work for two years each in chemistry and biology. Usually this course of study will occupy from three to four years.

It is evident that the course of medical study which will correspond to such a preparation for entering upon it, must be higher than that of any medical school in this country. Another indication of what is to be done is given by the plan of the hospital, which is arranged to lodge the graduating class, on the supposition that the last year of the medical studies will be devoted almost entirely to clinical work. Whether it is intended that those

students who do not matriculate for the B.A. degree, but pass the lower examination, shall be placed on an equality with the regular matriculants, so far as the degree of M.D. is concerned, is not known, and probably not yet decided, but it seems to us that they should not.

What the educated medical profession of this country hope and expect from the Johns Hopkins University is that it will make good use of the unrivalled opportunity which it has to give facilities for higher medical education such as do not exist at present in this country, and that it will not be turned from this by a desire to have a large number of medical students and graduates.

We have some very good medical schools in the United States, but we need one where the best men who can be found, with the best appliances obtainable, will devote themselves, not to the rivalling other schools in the manufacture of medical practitioners, but to supplementing the work of the best of the other schools; to training men for original research, or as teachers, and to promoting the scientific as well as the practical side of medicine.

The success of such a school must be reckoned by the quality and not the quantity of its graduates, and it seems to us that the degree of Doctor of Medicine of the Johns Hopkins University should be made equal at least to any similar degree of any institution in the world, even if not more than one man a year can be found qualified to receive it.

LOCOMOTOR ATAXIA AND SYPHILIS.

IN a discussion before the Therapeutical Society of Paris, recently, the relation between syphilis and tabes was warmly disputed. The weight of numbers was opposed to that view which regards the sclerosis of the cord as dependent on syphilitic infection. M. Edouard Labbé, has observed many cases of locomotor ataxia, in subjects having a syphilitic history. M. Gueneau de Mussy denies that there is any necessary connection between the two maladies. Dujardin-Beaumetz strongly opposes the theory of a causative relation, and maintains that Fournier's position on this point is untenable. Martineau avows his belief that syphilis is increasing year by year, and hence an infection may be suspected in doubtful cases. French opinion on this subject is divided, therefore; in Germany, the weight of authority is for the connection between syphilis and tabes, and in England there is an increasing volume of opinion in favor of the same view. Not sufficient stress is laid by any of the observers above referred to, on the two conditions, which may be held responsible for the production of sclerosis.

There are cases, in which all the objective phenomena of locomotor ataxia are due to gummata, so situated as to involve the coördinating and sensory tracts. Such examples differ from the true disease in that the symptomatic development is not orderly and synchronous, and in the important feature, that rightly directed specific treatment effects a speedy cure. Such cases are, properly speaking, examples of syphiloma of the spinal cord, and not of true locomotor ataxia.

There is another group of cases, greatly more numerous, in which a peculiar state of the system induced by the long continued existence of syphilitic lesions, and by the action of the specific remedies, gradually brings about sclerosis of various organs. In such examples, the syphilitic infection performs a secondary part, and the specific treatment does not modify the changes in the cord. If syphilitic infection is so wide-spread and increasing as Martineau suggests, is not this the true explanation of Rosenthal's gloomy announcement that locomotor ataxia is becoming a remarkably common malady? Admitting this view, it is necessary to bear in mind the true causative relation in most cases, and not seek by a lavish use of the iodides and mercurials to remove lesions, to the production of which these agents originally contributed.

UTILITY OF TREES IN CITIES.

THE discussion on the utility of trees in streets and open spaces, which took place in the International Hygienic Congress, held at Geneva in August last, has given rise to a controversy which has been carried on in the columns of the Geneva press. Dr. Piachaud, who supported the conclusions of the Congress, endeavors to prove that trees in streets do more harm than good, by impeding the circulation of air and obstructing light. He maintains that they are unnecessary for shade, as there is always a shady side to the street, and he favors the radical measure of the removal of existing trees. Prof. Goret, of the University of Geneva, has taken the opposite ground, and his reply is notable for its plain, practical, common-sense exposition of the subject. It is true that, in the narrow, dark streets of many continental cities, it may not be judicious to plant trees; nor is it likely that the practice would be adopted where the local circumstances are unfavorable. A wise discrimination is required in this as in all other city regulations; but there can be no valid reason for an unqualified condemnation of the practice.

There are few American cities that do not, by practice, endorse the views of Prof. Goret. Our broad streets and low buildings make the use of trees highly advantageous. They are not only ornamental and pleasing in their effect, and a source of comfort by the protection they afford against the glare of the sun, but they serve to

temper the heat, protect against dust, cool the air and keep it moist. If not improperly located, they do not intercept light, the constant movement of the leaves allowing the rays of light to play freely through the foliage. The green tints rest and protect the eyes.

The evaporation from the foliage, which is most active in dry weather, has a very sensible effect upon the movement, temperature, and humidity of the atmosphere. It has been proved by actual observation that the evaporation from trees during the summer months, is equal to eight or ten times the amount of precipitation upon the areas shaded by them. Such being the case, the absorption of water by their roots, and its subsequent evaporation, must very materially affect the water in the soil, and moisten the air and lower the temperature.

Trees help to purify the air and soil, and this influence is nowhere more needed than in cities. The foliage absorbs carbonic acid from the atmosphere, and gives out oxygen; and the roots, as just stated, imbibe moisture, and absorb organic matter, which is one of the common sources of pollution of the subsoil of cities. The roots also assist mechanically in draining the soil, by perforating the deeper and less permeable strata, and thus furnish an outlet to moisture which would otherwise accumulate and produce dampness in the adjoining foundations.

In planting trees good judgment must be exercised. In narrow, dark streets they are unnecessary. They should never be planted too closely together, nor so as to come in contact with buildings. The tall varieties with spreading foliage should be selected. Those varieties which are the prey of insects and worms should be avoided. The practice of "topping" trees, which is so commonly indulged in by the "tree-butchers" which infest our cities, is ruthless and most injudicious. Trees thus treated are always injured and are unsightly, the branches become compacted together, the foliage so dense as to intercept the light, and the shade they afford so limited as practically to be of no value whatever.

As bearing on the above subject, it is interesting to note the revived activity of the Brooklyn Society, established for the purpose of promoting the planting and protection of trees. This Society has recently issued a circular containing suggestions to those who may feel disposed to aid in the effort to render the city more attractive, and, at the same time, to add to the comfort and pleasure of the people.

Still more recently there has been issued, by the Bureau of Education at Washington, a tract on the "Planting of Trees in School-grounds," which treats of the selection, planting, and care of shade and ornamental trees. The object is to introduce a means of culture, and to foster a spirit in the community tending to the encouragement of tree-planting and the protection of trees. "Many considerations of an obviously persuasive character," says the Commissioner, "may readily be adduced to encourage the practice of tree-planting, whether the subject be looked at from an economical, sanitary, or æsthetic standpoint." And this remark is equally pertinent to the necessarily limited and modified application of the practice in cities.

DIAGNOSIS OF UROGENITAL TUBERCULOSIS BY INOCULATION INTO THE ANTERIOR CHAMBER OF THE EYE.

SOME time before Koch's discovery of the bacillus tuberculosis, DAMSCH sought to make use of the inoculable properties of tubercular material in the diagnosis of doubtful cases of disease of the genito-urinary apparatus. Pursuing this line of investigation he made thirteen injections into the anterior chamber of the eye of the rabbit, using for this purpose, with every precaution preserved, the purulent sediment of seven clinically well-characterized cases of urogenital tuberculosis, in part of which the diagnosis was confirmed by autopsies. *In every case* there was developed in the course of three or four weeks tuberculosis of the iris. Control-experiments were made with purulent urine from non-tubercular cases of bladder disease in three instances, and in *none* was tuberculosis of the iris produced.

Subsequently, as already noted in these columns, Rosenstein discovered the bacillus tuberculosis in the sediment of urine from a case of urogenital tuberculosis. Whether or not it is the bacillus which is the infecting agent in these cases, the fact, if such it be, is of the extremest practical importance. For it is well known that we possess no other means of determining certainly the presence of urogenital tuberculosis, and this mode is exceedingly easy of application.

Recently (*Deut. med. Wochenschr.*, April 25th), Damsch has again made use of this inoculation method in the diagnosis of doubtful cases of urogenital disease in four cases, with the result of apparently confirming his original conclusions. In each the inoculations were made at the time when the symptoms of the disease were confined to suppurative cystitis. In two cases, iris-tuberculosis was developed in three weeks, and both patients whence the pus was derived developed general tuberculosis, evinced in one case by distinct renal tumor and pulmonary phthisis, and in the other by laryngeal and pulmonary phthisis. In the two remaining cases, the inoculation, though frequently repeated, was without result, the pus disappearing from the anterior chamber in a few days. One of the patients whence the pus was derived recovered from the intense hemorrhagic cystitis with which he was af-

flicted, in a few weeks, but the second disappeared from observation before recovery.

Damsch also inserted, without effect, into the anterior chamber, large numbers of non-tubercular substances, including uric acid and sodium phosphate suspended in water, gonorrhœal pus in .6 per cent. solution of chloride of sodium, furunculous pus, non-tubercular peritoneal exudate, lepra products, etc. Similarly abortive were attempts to inoculate the cornea and conjunctiva by numerous injections into them of uric acid in suspension, xanthin, guanin, kreatin, kreatinin, and hippuric acid, alone and in combination with pus.

These results are exceedingly important, and in view of the ease with which they can be practised should be early repeated, and the true value of such diagnosis-inoculations ascertained.

NAPHTHALINE AS A DRESSING.

IT seems unfortunate that some of the best dressings smell the worst. Iodoform quickly perfumes (?) an entire house, and for him who prefers a different smell, naphthaline is at least a change, if not an improvement. Fischer introduced it to the profession in 1881; and it has alternately been asserted and denied that it forms crusts and obstructs drainage, irritates the skin, is a feeble antiseptic, and favors erysipelas.

Rydygier (*Berl. klin. Woch.*, April 16, 1883) reports his experience as almost entirely favorable, and accounts for the differences of opinion by differences of application. He applies it in fine powder, covers it first with gauze and cotton soaked in a solution of corrosive sublimate, and then with parchment-paper, or other water-proof material. Thus employed, he finds that its asserted disadvantages disappear, except that it is somewhat of an irritant, at least when mixed with the secretions of the wound; yet not to any great extent, for in a successful case of hysterectomy he applied three drachms to the wound, and several tampons in the vagina, leaving them there for seven days. A little vaseline obviates entirely the irritation.

It is free from the occasional poisonous action of carbolic acid and iodoform, and is exceedingly cheap, especially as compared with the latter.

THE great usefulness to the profession of State Boards of Health organized like those of Illinois and West Virginia, is again exemplified in a recent action of the latter with regard to one W. H. Hale, an itinerant, whose headquarters are in New York City, where he publishes a newspaper called *Health and Home*, the object of whose existence is to advertise his own eminence. In the course of his wanderings he recently visited Wheeling, "for the purpose of delivering a course of lectures and attending to such office practice in his line of specialties as was required." The laws of West Virginia require such persons to register and pay a registration fee of fifty dollars, after he has shown a diploma from a regular medical school. The fee was promptly paid, but in response to the demand for a diploma, he could only furnish a certificate of registration in New York City, and a diploma from the American Eclectic College of Cincinnati—a diploma mill comparable to that which so long disgraced our own city under Buchanan. These were not recognized by Dr. Reeves, the Secretary, and Dr. Hale was compelled to seek other fields for conquest.

We hope our readers will note his name and methods.

SOCIETY PROCEEDINGS.

ONTARIO MEDICAL ASSOCIATION.

Third Annual Meeting, held at Toronto, June 6 and 7, 1883.

(Specially reported for THE MEDICAL NEWS.)

THE annual meeting of this Association was held in Toronto, June 6 and 7, in the Hall of the Department of Education of the Province.

In the absence of DR. MACDONALD, the PRESIDENT, through illness, DR. RICHARDSON was called to the Chair. This was the most successful meeting of the Association yet held, there being upwards of one hundred and twenty-five members present. The morning session was devoted to general business and the admission of new members. On reassembling, at 2 P.M., the reading of papers began, the first being

ON TRAUMATIC TETANUS,

by DR. BURT, of Paris, with a case exhibiting the effects of neurotomy. The tetanus occurred from a wound on the outer side of the forearm. The musculo-spiral nerve was divided above the elbow, and the cutaneous filaments severed by a transverse incision through the skin below the elbow, thus completely insulating the wound. Before the operation, spasms had been taking place every few minutes; after the operation, they were at once reduced to twelve or fifteen a day, and ceased entirely in a few days. Complete recovery followed, the patient being able to resume her usual occupation in three months.

DR. CAMPBELL, of Seaforth, next presented a case of

PRIMARY LATERAL SCLEROSIS,

and gave in detail the history. The symptoms first appeared last July. Ergot was found of greater benefit than any remedy tried.

SOME OF THE USES OF JABORANDI

was the subject of a paper by DR. MACKAY, of Woodstock. He gave condensed reports of its use in tonsillitis, asthma, congestion of the lungs, scarlatina, measles, diphtheria, and common colds, in all of which he had derived most signal benefit from it. He had never had occasion to administer more than ʒij of the fluid extract in divided doses; usually one dose of ʒss proved sufficient to cause profuse diaphoresis.

DR. MULLIN, of Hamilton, had given it in one case of common cold, producing free diaphoresis. But there was free albuminuria for the next twenty-four hours, whether or not due to the jaborandi he did not

know. He thought it desirable to inquire into its action on the kidneys.

DR. POWELL, of Edgar, drew attention to the paper by Fordyce Barker, of New York, on jaborandi in puerperal uræmia. Of five cases to which it was given, four died. The opinion was almost unanimous, that a remedy producing such great prostration should not be given, except under special circumstances.

The next paper was on

THE TREATMENT OF TALIPES BY THE WEDGE PLASTER SPLINT,

by DR. BURROWS, of Lindsay. He described several successful cases in which this method had been adopted.

DR. WOOLVERTON, of Hamilton, treated a case of double talipes varus by bringing the foot into proper position by the hand, applying a soft flannel bandage, and over this a fixed plaster dressing. This was allowed to remain for six weeks and a similar dressing again applied. After the application had been used three times the tendo Achillis was cut. The recovery was perfect. This treatment was recommended not to be used before the age of six months by the authority who introduced it.

DR. ZIMMERMAN, of Toronto, thought that it made great difference as to the results of treatment, whether the child had walked.

DR. WOOLVERTON then read a paper on

FATTY DIARRHŒA,

with the history of a case that came under his care last summer. The patient, a woman, aged thirty-three, was in the habit of drinking much liquor. From ten to twelve ounces of fat were passed in twenty-four hours. It was semifluid, and of very offensive odor. It disappeared from the stools in a few days, to reappear for a short time some weeks later. It has not troubled her since. No fatty food had been taken, owing to a distaste for it. On microscopic examination, the fat appeared to be emulsified. Whether it was from the food or secretion, at the expense of the system, was not known. Dr. Wells, of New York, in 1854, reported a case of fatty diarrhœa, in which there was no effect on the amount or character of the fat evacuated by the consumption of or abstinence from fatty food. The sago-like mucus sometimes occurring in the stools in certain diseases of the bowels should be differentiated from fat.

DR. SHEARD, of Toronto, said he had made post-mortem examinations on three cases in which there was fatty diarrhœa at the time of death. In one there was cancer of the pancreas; in another, cirrhosis of the liver, kidneys, and pancreas; in the third, the mesenteric glands were diseased. In all these cases there was obstruction of the absorbents either from pressure or disease. The digested fat in the stools in the case of cancer indicated the agency of other fluids than that of the pancreas in the digestion of fat. He thought that fat in the stools was due to non-absorption, rather than to secretion.

DR. GROVES, of Fergus, read a paper on

A NEW METHOD OF REMOVING SOLID OVARIAN TUMORS,

with a case in which the tumor was thirty-eight inches in circumference and weighed twenty-one pounds. In operating, the tumor was enucleated, and the opening in the peritoneal covering of the tumor sutured to the peritoneal margin of the abdominal incision, which was very extensive on account of the large size of the tumor.

DR. MCNAUGHTON, of Erin, showed

A NEW SPLINT,

applicable, he thought, to all fractures of the forearm.

DR. CARSON, of Toronto, said: The late Professor Syme, of Edinburgh, always used a splint one inch wide, well padded, placed along the front of the forearm, and no one could claim better results.

DR. POWELL urged the necessity of thorough reduction in Colles' fracture, if possible. He preferred a splint with a slight pistol curve.

DR. RICHARDSON said a certain degree of deformity was unavoidable in many cases of Colles' fracture, and in the majority there was some rigidity for some time.

DR. C. K. CLARKE read a paper on *A Case of Hystero-epilepsy*, at present in Rockwood Asylum, Kingston. The symptoms were very marked.

EVENING SESSION.

DR. D. CLARK, Superintendent of the Toronto Asylum, *Vice-President*, in the chair.

DR. WORKMAN read a most interesting paper on *Aphasia*, relating especially to several cases of unusual interest met with in his long and varied experience.

DR. GRAHAM, of Toronto, read a paper on

THE BACILLUS OF TUBERCULOSIS.

It must be admitted, he said, that the majority of the more distinguished pathologists had by investigation strengthened the position taken by Koch that the bacilli described by him were peculiar to tuberculosis, and that they are immediately connected with the production of the disease. The questions they, as physicians, were interested in, were: 1. Can phthisis be diagnosed by means of the presence of bacilli in the sputa? 2. Has the number of bacilli any relation to the prognosis? 3. Has the discovery aided us to any extent in the prevention and treatment of this formidable disease?

Investigations led to an affirmative answer to the first question.

He then gave the results of the examination of the sputa of forty patients which he had examined. The conclusions arrived at by him from these experiments were: 1. That bacilli are found in the sputa of almost all, if not all, cases of phthisis; it was doubtful if there was any case of active disease in which bacilli will not be found, provided the sputa came from the lungs, and five or six examinations were made. 2. They were found on the first examination in three-quarters of the cases. 3. The presence of the bacilli is a positive evidence of the disease. 4. There are doubtful cases in which the examination of the sputa for the bacilli will be of decided value in arriving at a correct diagnosis. 5. As to prognosis, it was found that the number was in proportion to the amount and rapidity of the process of destruction. 6. It might be said as a general rule that in the more chronic cases bacilli were fewer and, he thought, smaller. His experience convinced him of the contagiousness of the disease, of which he gave instances.

DR. COVERNTON asked if bacilli were the cause of phthisis, or were only present because the soil was suitable for them. He thought phthisis had been produced by indifferent inoculation.

DR. SHEARD said it needed great care in preparing the sputa for examination for bacilli. Fat-crystals were liable to be mistaken for them. He would not accept a section of tissue for examination unless it had been submitted to ether to dissolve any fat that might be present.

DR. ZIMMERMAN asked if tuberculosis was to be distinguished from phthisis, and if syphilitic phthisis was tuberculosis.

DR. FERGUSON, of Toronto, had collected the following statistics: In 2,500 cases examined by various authorities bacilli were found in over 2,300; of the

balance, 74 cases were doubtful, and in the rest no bacilli were found. In many of the latter the examinations were defective from various causes. Most observers were agreed that the greatest number of bacilli were found in worst cases, in which also grouping of the bacilli was frequent. Of 51 observers, 37 agree as to the contagiousness of tuberculosis; 9 were doubtful, and 5 were opposed to the view.

DR. MCPHEDRAN thought if bacilli were admitted to be a cause of tuberculosis, then the disease would of necessity be contagious, as the bacilli were readily transmitted from one person to another. He had examined the sputa of all cases coming under his care lately, finding bacilli in all but one, and that had been examined only once. He asked if fat-crystals should not be found in the sputa of chronic bronchitis as well as in that of phthisis.

DR. MULLIN asked how it was that only the bacilli of phthisis withstand the action of the strong solution of nitric acid used. He thought many cases could be cited, opposed to the theory of contagion. He thought it utterly improbable that bacilli should remain quiescent for so long a time, as some affirmed the term of incubation might last; if so, they were wholly unlike any other disease germs.

DR. RICHARDSON had always considered the disease contagious, long before bacilli were thought of. He was confirmed in that opinion by recent investigations. He did not think the long period of incubation any serious obstacle. Syphilis will, after being many years dormant, be transmitted to others. He had considered cholera contagious before it was generally so thought to be. He has used inhalations for two years, and with very satisfactory results.

DR. CANNIFF, of Toronto, thought the theory of contagiousness a very attractive one, but was not yet convinced. The history of Brompton Hospital militated against it.

DR. GRAHAM, in reply, said there was no difficulty in distinguishing fat-crystals from bacilli. He could not understand how Spina (who had been referred to during the discussion) had not found bacilli in the cases (150) of tubercle he had examimed; it was incomprehensible. "He had read Spina's article within the last few days, and thought it contained nothing convincing." In answer to Dr. Mullin, he said it was the staining that made the bacilli resist the nitric acid solution. The bacilli of leprosy were also unaffected by the acid.

DR. STRANGE related a case of

ACETONÆMIA.

Diabetes mellitus had been diagnosed, and the following evening the young man became suddenly comatose, and died in ten hours. He entered into the history of this disease and the general opinion as to its pathology.

DR. ZIMMERMAN said that some attributed the coma to fat emboli instead of the acetone in the blood.

THURSDAY, JUNE 7TH, SECOND DAY.

The Association reassembled at 10 o'clock, THE PRESIDENT, DR. MCDONALD, of Hamilton, who had just arrived, in the Chair.

DR. BATTERSBY, of Port Dover, read a paper on *Umbilical Hernia*, and DR. MITCHELL, of Enniskillen, one on *Some Cases of Poisoning*, in which three cases were related.

THE PRESIDENT then delivered his

ANNUAL ADDRESS,

in which he dealt with the objects of the Association—the promotion of the interests of the profession in Ontario. The Association occupied a place between the local Associations and that of the Dominion. He thought the meeting should be held in the east and west of the Province alternately with Toronto, as tending to promote its usefulness by awakening the interest of the various places in which it met. He next referred to the relations to the homœopaths. There was no change in the views of the general profession as to the doctrines of Hahnemann, not one of which had as yet been proved. The College of Physicians and Surgeons, the only body that has the power to grant license for practising in this Province, obviated any difficulties as to irregular practitioners; it existed to protect the public from such. The question of a library and museum in connection with the Association was next dwelt upon; and lastly the question of the use of alcoholic stimulants in treatment of disease, a matter strongly urged upon the attention of the Association by the Women's Christian Union, who asked for a reinvestigation of the therapeutic properties of alcohol. The President said the request could be quite properly entertained, since the opinions of many eminent medical men had undergone no little modification on this question of late years.

After the conclusion of the address, DR. RADFORD, of Galt, showed a small boy with chorea which had failed to yield as yet to treatment.

DR. ZIMMERMAN recommended circumcision if the prepuce was long.

DR. MCPHEDRAN, of Toronto, showed a boy, aged 7, suffering for two years with an eruption closely resembling Hebra's prurigo.

AFTERNOON SESSION.

Cancer of the Larynx was the subject of a paper by DR. RYERSON; *Hip-joint Disease* by DR. FERGUSON; and *Enteric Fever* by DR. CASSIDY.

DR. DAVIDSON, of Toronto, read a paper on a

CASE OF SUPERFŒTATION.

Delivery took place; one fœtus being four months and the other four weeks old. No decomposition in either. The catamenia had not ceased during the pregnancy. From the condition of each fœtus and the continuance of the catamenia, he considered it a case of genuine superfœtation.

DR. CAMERON believed it to be a case of twin pregnancy with arrested development of one ovum.

REPORTS OF COMMITTEES.

The Public Health Report urged the importance of keeping up the public interest in sanitary matters and recommended the teaching of hygiene in the public schools.

The temperature question, which was submitted to the Association in the President's Address, was referred to a special committee, to report at the next meeting.

A resolution was adopted asking the Government to have health boards and medical health officers appointed for each municipality.

The report of the Committee on Ethics condemned, in the strongest terms, consultations with homœopaths and all irregulars, as well as advertising in any form. There was not time to act on the report, so it was referred back to the Committee to be brought up again next year, but the strong approbation evinced, as each clause was read, went to show an attitude of unswerving hostility to any departure from the highest standard of ethics.

Steps were taken towards the organization of a museum in connection with the Association, and the President and Secretary appointed a committee to memorialize the Council of the College of Physicians and Surgeons on the subject, and to bring the matter before the government with the request for funds to aid in its establishment.

Two specimens of rare interest were shown among the collection of pathological material on exhibition, one,

A HEART WITH ONLY ONE VENTRICLE AND ONE AURICLE,

from a girl aged 12, by DR. A. A. MACDONALD, of Toronto. The auricle had a rudimentary partition, but its cavity was really one chamber only. The child was always cyanosed and not able to go about much.

The other specimen was

CONJOINED TWINS,

born at Queen Charlotte's Hospital, London, England. They weighed five pounds and were fourteen inches long. The specimen was loaned to the Association by Dr. Ralph Leslie, of England. The union extended from the manubrium to near the pubes. There was only one funis. Both children were well developed.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—DR. W. CLARK, of Toronto.

Vice-Presidents.—DRS. WORTHINGTON, of Clinton; PHILIP, of Brantford; MCGILL, of Osborne; and RICHARDSON, of Toronto.

Recording Secretary.—DR. WHITE, of Toronto.

Treasurer.—DR. GRAHAM, of Toronto.

Corresponding Secretaries.—DRS. GRAHAM, of Brussels; MACKAY, of Woodstock; I. H. CAMERON, of Toronto; and AYLESWORTH, of Collingwood.

The Association then adjourned, to meet next June in Hamilton.

A *conversazione* was held in the evening in the galleries of the Education Department, in which the Annual Exhibition of the Royal Canadian Academy of Arts and the Ontario Society of Artists is at present being held. About eight hundred were present, and the evening was spent viewing the exhibition, which was extensive and contained many works of rare merit.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, May 22, 1883.

THE PRESIDENT, T. M. MARKOE, M.D., IN THE CHAIR.

DR. A. C. POST presented a patient upon whose hands he had performed nine operations for the relief of cicatricial contractions from burns. The case was made the basis for the following paper, entitled

AN EXTREMELY COMPLICATED CASE OF CICATRICIAL CONTRACTION FROM BURNS.

(See page 707.)

DR. SANDS said he had operated twice for the relief of contraction of the fingers caused by a burn of the palmar surface of the hand, and in both cases he had had the advantage of Dr. Post's counsel and assistance. He performed operations similar to those which had just been described, and was surprised to find how freely the cicatricial tissues could be divided without causing mortification. In both of these cases it was nesessary to resect several of the joints in order to bring the fingers into a straight position. Subsequently, the fingers of those joints which had been resected were considerably shortened, still their position was very much improved. He had noticed that where resection had been made motion was destroyed, and he would like to ask Dr. Post if he had succeeded in restoring any amount of motion in these resected joints.

DR. POST replied that absolute rigidity had been prevented, and that it was rather desirable that very free motion should not be established because there are no lateral ligaments, and free motion could not be established without making the movements of the fingers wabbling or flail-like.

THE PRESIDENT asked if, in exsection, the head of both bones was removed.

DR. POST said that only the distal end of the proximal bone was removed.

THE PRESIDENT asked if Dr. Post proceeded in the same way for contraction of the palmar fascia.

DR. POST replied that he performed substantially the same operation. He also thought that Mr. Adams, of London, was in error in speaking of Dupuytren's contraction as being always due to gout, as he had seen it arise from a variety of traumatic causes.

DR. G. A. PETERS said he had recently had a case in which this contraction was brought about by rolling.

DR. POST remarked that in traumatic cases the integument is firmly adherent to the fascia, and in the cases which he had seen, it was not an easy matter to make the incisions without dividing the fascia.

THE PRESIDENT said that he had recently seen two cases with Dr. Abbe, who performed the operation described by Dr. Post, and he was surprised at the moderate amount of inflammation which followed the multiple incisions.

DR. PETERS asked how long counter-extension was maintained.

DR. POST said, sometimes two or three months, alternating with passive motion. He further remarked that there was a curious feature in all cases of cicatricial contraction, which was that, the parts having been bound down, the process of restoring them to their original position by passive motion is very painful.

INTESTINAL OBSTRUCTION.

DR. SANDS presented two specimens removed from the body of a man on whom he had performed the operation of inguinal colotomy for the relief of intestinal obstruction. As would be remembered, in the month of March, 1882, he exhibited this patient to the Society three weeks after the operation. It would be remembered, also, that the patient had had a fecal abscess to the left of the median line in the umbilical region; that the abscess had closed, and that coincident with closure of the abscess, there appeared signs of intestinal obstruction, which were complete at the time when colotomy was performed. The operation gave entire relief, and the man was able to be about for nearly one year. It was noticed, however, that during all this time he was exceedingly harrassed by an inability to control the artificial opening. This opening was not more than one-third of an inch in diameter, but no form of bandage or truss had any effect in preventing the feces, which were very thin, from escaping. Owing to this infirmity he was prevented from pursuing his occupation. Dr. Sands lost sight of the patient for a long time, but finally heard that he was again suffering from intestinal obstruction. When he saw him, he found that the escape of feces from the artificial anus was imperfect, and he therefore enlarged the opening somewhat by the use of sponge tents, giving considerable relief.

On the fifteenth of April last the patient died, and an autopsy was made on the following day. Death resulted from peritonitis, the cause of which did not seem to be quite clear, although most probably it was due to inflammation occurring at the site of the previous abscess. On opening the abdomen, the coils of intestine were found almost everywhere adherent. Recent lymph, mixed with sero-purulent fluid, covered the surface of the intestines, and the pelvic cavity contained a certain amount of turbid fluid. No gas escaped when the cavity was opened, and there was no reason to believe that the peritonitis had been occasioned by perforation of the intestine. The site of the previous

abscess was found to be the seat of a phlegmonous inflammation, apparently on the verge of suppuration, while opposite to this the large intestine was found firmly adherent to the abdominal wall, the part attached being the descending colon a short distance above the sigmoid flexure. There was also noticed a very firm adhesion between this part of the descending colon and a segment of the small intestine, which subsequently proved to be the jejunum. The large intestine above the sigmoid flexure was enormously distended. The diameter of the distended gut was not measured, but was estimated as being three or four times the normal calibre. This distention extended from the cæcum to a point very near to the sigmoid flexure, where the occlusion of the large intestine was complete. A segment of the abdominal wall was removed corresponding with the site of the adherent large intestine, which was also removed, together with a piece of the small intestine.

It was noticed that the feces contained in the large intestine were remarkably soft; such are commonly found in the small intestine. In the large intestine below the point of complete occlusion was found a small amount of feces of firm consistency and dark color. The artificial anus was found pervious, the opening being about one-fourth of an inch in diameter, and it seemed difficult to understand why the feces did not escape from it. A portion of the abdominal wall, corresponding to the site of the artificial anus, was also removed. The two specimens were presented. The first consisted of a portion of the large intestine adherent to the abdominal wall, a portion of the integument, and a piece of adherent small intestine. The most interesting point connected with this specimen was the presence of a large opening, oval shaped, and one inch in diameter, leading from the colon into the jejunum. Beside this there were two abnormal channels; one narrow, fistulous tract, starting from the large intestine and adjacent to the opening which led to the small intestine, and passing through inflammatory products to a point in the large intestine about an inch below the point of complete obstruction. Just above the complete obstruction there was also a small orifice connected with a smaller tortuous channel, communicating with the small intestine.

The second specimen showed the parts concerned in the formation of the artificial anus. The operation had been performed by cutting through the peritoneum. Pains were taken not to examine too curiously the contents of the abdomen, and Dr. Sands opened the distended intestine, not knowing precisely what it was, but he believed it to be the cæcum from the size and position of the gut, and from the fact that it seemed to be fixed to the posterior abdominal wall. The specimen showed that the opening was made into the front wall of the cæcum, near the lower wall of the cul-de-sac. The mucous membrane of the cæcum and the vermiform appendix was considerably thickened, but beyond this no abnormal changes were noticed.

It was interesting to consider what the course of the feces must have been in this patient during life. Instead of passing in the usual manner through the entire length of the small intestine, they must have been diverted to a great extent, through the large opening already described, into the large intestine, just above the junction of the descending colon with the sigmoid flexure. Being prevented from passing downward toward the anus, they must then have traversed the colon in a backward direction toward the cæcum. The ileo-cæcal valve being short, and the artificial anus very narrow, distention of the colon naturally followed, although it seems as if this might have been relieved by dilating the artificial anus, and by the use of enemata.

Perhaps it was in consequence of the fact that the feces did not traverse the small intestine, that the general condition of the patient deteriorated, leading to rapid emaciation. When the large opening between the large and the small intestine was established it was impossible to say, but it was plain that the fecal abscess was connected with the large intestine, because the small intestine was not adherent to the abdominal wall. No neoplasm was found in any part of the abdominal cavity, nor was there any foreign body found in the discharges at the time of the opening of the abscess which could explain the perforation.

Whether the two perforations—that of the large intestine toward the external surface, and that of the large intestine toward the small intestine—had the same cause—namely, follicular ulceration of the large intestine—could not be stated, but this was rendered possible by the several lesions of the large intestine.

The case was remarkable in the fact that an abscess allowing of the escape of the entire feces should close spontaneously in spite of complete occlusion of the sigmoid flexure, and then give rise to symptoms which required the formation of an artificial anus.

Examination of that part of the mucous membrane of the large intestine which corresponded with the site of the former abscess showed no cicatricial tissue to mark the previous existence of an ulcer in that situation.

The other lesions found were fatty liver with commencing cirrhosis, and a cyst in one of the kidneys, without any other evidence of renal disease. The man was fifty-nine years of age at the time of his death.

The PRESIDENT remarked that not unfrequently tubercular ulcers perforated the wall of the intestine, and afterward the feces found their exit through another part of the intestine, perhaps far distant from the original point of rupture; but in the case reported by Dr. Sands, there was no evidence of tubercular ulcers. The President had one case, that of a young lady, suffering apparently from tuberculosis, in which the duodenum opened into the colon, and the patient perished simply from lack of nutrition, and with evidence of peritonitis extending over weeks and months.

DR. BRIDDON had an impression that diseases of similar character were not infrequent among colored people. He recollected that the late Dr. Whitall expressed to him that opinion, and showed him a case where an abscess of the abdominal walls was followed by a fistulous communication of the intestines with stercoral ulcers resulting in abscess, and stated that these cases were not uncommon, but that they were always fatal. Whether such ulcers were tubercular or not, he was not prepared to say.

DR. PETERS.—Probably yes.

DR. BRIDDON had a patient under observation who was admitted to the Presbyterian Hospital with a sinus at the umbilicus, giving exit to flatus and fluid feces. He was unable to obtain any history of diarrhœa or of dysentery, or very much pain; and on examining the abdominal walls, the only spot of induration was in the middle line, between the umbilicus and pubis. That led him to make a vaginal examination, and he found a swelling in Douglas' cul-de-sac, but he was unable to make out whether it was the result of infiltration or was a retroverted uterus. The retroverted uterus could be made out, but the mass seemed to be too large for that condition alone. He was able to introduce a sound four or five inches into the fistulous track, and he believed that it passed directly into the intestine.

DR. POST said that a number of years ago, he reported a case to the Pathological Society, that of a

gentleman who was thrown from a buggy in Central Park, and received a severe contusion in the loins, which led to the formation of an abscess with which the descending colon communicated, and for the remainder of his life he passed his feces through this fistulous opening. On examination of the body at the autopsy, he found quite a close stricture, which had interfered with free evacuation of the bowel in either direction. The greater part of the feces passed through the fistulous opening, and always where there was solid matter it passed with pain and difficulty. He thought that, probably, free colotomy would have benefited such a patient.

DR. BRIDDON asked Dr. Sands whether he regarded the difficulty which his patient experienced in retaining feces, depended upon the location of the artificial anus, or upon the fluid condition of the feces from the communication with the small intestine.

DR. SANDS said that he did not know, but he imagined that it depended considerably upon the situation of the artificial anus, and he should regard this as a great drawback to the operation of inguinal colotomy.

DR. BRIDDON remarked that he had not seen a case in which the patient experienced any trouble in retaining feces after lumbar colotomy.

ACUTE OSTEO-MYELITIS FOLLOWING SLIGHT INJURY OF THE ANKLE.

DR. MCBURNEY presented the leg and foot, removed a few days since from a child nine years of age, which illustrated how extensive might be the damage done by a neglected periostitis. Two months ago the child, while jumping the rope, struck the ankle with the other foot, which gave her extreme pain and caused her to fall. Curiously enough, the child was allowed to go to school on the next day, and continued to do so four weeks, but at the end of that time the pain and suffering were so intense that a physician was sent for, who regarded the case as one of cellulitis, and treated it as such by the application of poultices, subsequently made some incisions, and gave vent to a large quantity of pus. The case, however, did not progress favorably, and subsequently Dr. McBurney was invited to see it in consultation. He found the foot exceedingly œdematous, and also the leg up to the knee, and the skin was covered with blebs. The child's general condition was very bad; there was alternating high and low temperature, with sweats, etc.; quite a large granulating orifice on the inner aspect of the limb, and a similar one on the other aspect. There was evidence of extensive denudation of bone, and the epiphysis of the tibia at the ankle was separated. The joint was opened; the articular cartilages were more or less destroyed. Dr. McBurney amputated the limb at the middle of the leg, closed the wound with carbolized silk sutures, powdered it with iodoform, inserted a drainage-tube at the lower angle, and applied a peat dressing over the whole. The temperature had not risen above 99° since the operation. Previous to that it fluctuated between 99° and 102°, accompanied by sweats and general constitutional disturbance. The dressings had been changed at intervals of varying length, the first being allowed to remain five days, at the end of which time the drainage-tube was removed, and the progress of the case had thus far been eminently satisfactory.

URINARY CALCULI.

DR. BRIDDON presented specimens, and related the history of a case as follows: On Sunday afternoon he was called to the Presbyterian Hospital to see a child two years old, who had suffered eight or nine months ago from an attack of abdominal pain, which had been called renal colic. Since that time he had had frequent attacks of pain, frequent micturition, and a disposition to pull upon the prepuce. Two or three days before admission he had an attack of retention of urine which was relieved by the catheter. On the night before admission he attempted to empty a distended bladder, but only with partial success. On the afternoon of the day of admission the bladder was distended up to the umbilicus, and the house-surgeon attempted to introduce a catheter, but found an obstruction about three inches from the meatus, which he was unable to overcome, and the bladder was then aspirated. Dr. Briddon saw the patient at nine o'clock in the evening, passed a silver catheter, No. 6, down to the obstruction, and without material difficulty succeeded in introducing the instrument into the bladder and emptied it. The child's temperature that night was 106° F., a fact for which he was not able to account. On the following day the temperature was 105° F., and the bladder was again distended. He introduced an instrument, encountered an obstruction, but whether it was in the prostatic portion of the urethra or in the bladder he was unable to say positively. He performed median lithotomy, encountered no obstruction in entering the bladder, readily came upon the smaller of the two calculi presented, which was exceedingly minute, and removed it. He then withdrew the staff, introduced the finger, and found the large calculus lying in the incision; probably it was the calculus which had been impacted within the urethra, and it was about five-sixteenths of an inch in diameter.

DR. BRIDDON also presented a specimen of the same character, which he obtained in 1861. He was called to visit a child two years and seven months old, who was suffering from retention of urine. He introduced a catheter, detected a small calculus, but found no difficulty in drawing off the urine. On the following day he was about to proceed to remove it by lithotomy, and as soon as he drew the prepuce down, he found a small calculus impacted in the meatus, about half of it projecting, and it was easily removed. After its removal, he introduced a sound into the bladder and detected a large stone, which he removed by the lateral operation.

He was unable to explain the high temperature which occurred with the retention of urine in his first case.

DR. POST remarked that retention of urine was a cause for considerable constitutional disturbance, and probably of itself would explain the elevation of the temperature.

DR. BRIDDON thought it unusual for retention to be associated with such a high temperature.

DISLOCATION OF THE HEAD OF THE FEMUR IN ACUTE RHEUMATISM.

DR. C. T. POORE narrated a case, as follows: On Tuesday last he was called to see a boy, seven years of age, who had had inflammatory rheumatism for four months. As a result, there was contraction of both knees, and the left thigh was flexed and adducted considerably. On examining the limb very carefully, he found that the head of the femur was dislocated upon the dorsum of the ilium; he thought that there was no doubt that it was a case of acute rheumatism, and that the hip had been out for at least six weeks. The dislocation was reduced, but it recurred. He proposed to divide the tendons and place the patient in a fixed apparatus. The acute attack of rheumatism involved both knees and the left hip—which was the one that was dislocated—and also the elbows.

THE PRESIDENT said it would seem that such a dislocation could not occur without some change in the acetabulum. The inference would be naturally that there was some coxitis present.

DR. POORE said he thought there was no doubt that it was a case of simple acute rheumatism. There certainly was no evidence of morbus coxarius. Further, the hip-joint has been known to be dislocated in acute diseases; for example, in typhoid fever, a case of which was recorded last year in one of the Liverpool journals.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Thursday, June 7, 1883.

THE PRESIDENT, R. A. CLEEMANN, M.D., IN THE CHAIR.

DR. FRED. C. SHEPPARD exhibited the uterus and appendages removed post-mortem from a case of

INTERSTITIAL OR TUBO-UTERINE FŒTATION,

and read the following report:

Through the courtesy of Dr. George S. Hull, of Chambersburg, Penna., I am enabled to present, this evening, the post-mortem specimens of one of the rarer forms of extra-uterine pregnancy. The history of the case is given in such a clear and complete form by Dr. Hull, that I will read it in his own words. "(April 11, 1883.) A few days ago it fell to my lot as Coroner, to hold an inquest on a colored woman who had died suddenly. Vomiting followed by death, together with a history of family troubles, led her friends to suspect her husband of poisoning her."

"About three A.M., pains had set in in the left inguinal region accompanied by severe vomiting; I could not learn whether the pain preceded the vomiting or *vice-versa*. A physician was sent for; he did not go but sent three ¼ grain morphia powders. She took one every hour, seemed easier, and the vomiting ceased. At noon becoming very weak, the doctor was again sent for, responded in person, and found the patient pulseless at the radials; he ascertained that she had been constipated for about a week, and made a diagnosis of obstruction of the bowels; he gave five compound cathartic pills, and ordered an enema. In an hour the patient was dead."

"*Autopsy:* Peritoneum inflamed (recent—no pus), stomach empty save the pills, which were liquefied, *Intestines* normal. About two quarts of clotted blood were found in the abdominal cavity. The womb was ruptured, a small circular rent in the fundus about the left cornu."

"The uterus was removed and the rent enlarged; a fœtus of about three months with membranes entire was found. The placenta seemed attached at the point of rupture."

"The pregnancy seemed to be interstitial, the tube being involved. The lower half or two-thirds of the uterus was much hypertrophied and contained two or three teaspoonfuls of muco-pus, which could be pressed out at the os uteri. There was no communication between the pus-cavity and the cavity containing the fœtus. The uterus was not adherent to the other organs."

A sketch by Dr. Hull shows the uterus inclined to the right side, the fœtal sac occupying very nearly the normal position of the fundus, and the point of rupture a little to the left of the line of the umbilicus.

"It occurred to my mind that the rupture was spontaneous, causing the vomiting and pain of the night; however, the woman had eaten of sauer-kraut for supper, and it might have caused the vomiting, and that in turn the rupture. The morphia allayed the symptoms for a time, but the hemorrhage was slowly going on, and peritonitis setting in; the former predominating, death took place from loss of blood. She was the mother of one child, and was to all appearances in good health up to the time of the accident."

An examination of this very interesting specimen shows an enlarged womb with a dilated cavity, the walls of which are hypertrophied to a thickness of seven-eighths of an inch; lining this cavity is a structure which appears to be a true uterine decidua: the os is small, with an irregular stellate outline, and is perfectly patulous; the cervix is partially absorbed. The right ovary is small and flattened; the left of about normal size; at the point of entrance of the left Fallopian tube is a large intra-mural cavity, which contained the fœtus; the outer wall of this cavity is exceedingly thinned, and presents ragged edges at the point where rupture took place; to the inner wall are attached some remnants of the placenta; no communication can be detected between the fœtal cyst and the uterine cavity. The fœtus is apparently of from three to four months, and is presented with the membranes unbroken.

To cases of this class the terms interstitial, tubo-uterine, utero-interstitial, and parietal have been applied. Dr. Parry, in his work on *Extra-Uterine Pregnancy*, classifies them under the head of "tubo-uterine, or those in which the germ is arrested in that portion of the tube which passes through the uterus." They are very rare. An analysis by Hecker (quoted by Parry) shows twenty-six cases out of two hundred and twenty-two, and Parry in his analysis of five hundred cases of extra-uterine pregnancy, finds but thirty-one of the tubo-uterine variety, but two hundred and thirty of his cases are grouped under the general head of doubtful. Mr. Alban Doran, (*Obstet. Trans.*, vol. xxiv., 1882, p. 234) has been able to find but six specimens in all London, though he states that "we see a goodly array of the more frequent tubal form in almost every museum." I will not occupy your time this evening by referring to the question of pathology or of diagnosis, as both points cover the entire ground of extra-uterine pregnancy, and will be discussed in a future paper.

The proper treatment to adopt in these cases is however a point of great interest, and merits notice. A ruptured extra-uterine fœtal cyst may cause death instantaneously, as in the case of the English actress mentioned by Dr. Chabazian (*Obstet. Trans.*, 1882, p. 157). "She was taking an ice in the Bois de Bologne, she fell down suddenly, and she was dead." Poisoning being suspected, an autopsy was performed. No trace of poison was detected, but the ruptured pouch of an extra-uterine fœtation showed the cause of death. In this case, of course, there was no time for surgical interference, but in many, as in the one reported this evening, an appreciable interval elapses between the first symptoms and the fatal issue. The diagnosis being made, what would be the proper course to pursue? Unquestionably, laparotomy. An exploratory incision would at once reveal the true condition of affairs, and the surgeon could either incise the cyst, turn out the contents, ligate the bleeding points, suture the edges to those of the abdominal wound, and establish drainage; or, if thought better, remove entire the uterus and its appendages. Either plan would offer a very fair prospect of recovery, while if left without surgical aid the patient would be doomed to inevitable death.

A number of points of interest present themselves in the study of this interesting case, but the limits of a paper of this character forbid us taking them up. I might merely call your attention to the large quantity of blood; Dr. Hull states, about two quarts exuded from a comparatively trifling rent. This fact has been repeatedly commented upon by other observers. Dr. Parry states that some of the most severe hemorrhages occur when the orifices are very small, and cites a number of instances in which from several pounds to two and a half gallons of blood have been found in the

abdominal cavity after rupture of the extra-uterine cysts.

In conclusion, let me recall to your mind Dr. Hodge's case. His patient went to the eighth month, labor was brought on by dilating the os uteri, and the child delivered by rupturing the septum between the uterine cavity and the fœtal sac; the child was delivered by the natural passages. The child lived two hours, and the mother made a complete recovery.

DR. B. F. BAER had examined the specimens, and felt a doubt of its having been of the usual form of tubo-uterine gestation. That form is the rarest, and is considered the least dangerous because not so liable to rupture in consequence of having the muscular tissue of the uterine wall to strengthen it. In Dr. Hodge's case, the septum of uterine tissue between the uterine cavity and the fœtal sac was so thin that it could be scratched through with the finger. As the case reported by Dr. Sheppard terminated by rupture about the third or fourth month, it resembles a tubal in that particular. The question of operative interference is very interesting. In this case, as ten hours elapsed between the accident and death, an operation would be justifiable if the diagnosis could have been established.

DR. ALFRED WHELEN remarked that Miss Neilson lived ten hours after the first shock of her illness, and the published report of the autopsy stated the cause of the death to have been rupture of varicose ovarian veins.

DR. SHEPPARD, in closing the discussion, remarked that Dr. Parry classes all of this type of cases as tubo-uterine. The sac in this case was undoubtedly in the uterine wall, as the specimen shows. He had not been able to pass a bristle from the uterus into the Fallopian tube. As regards the possibility of the spontaneous stopping of the hemorrhage as a reason for postponing the operation, he would not consider it advisable to wait, for even when the laceration is very small, as in this case, the hemorrhage may, and probably will, be excessive; this hemorrhage is the cause of death in most, if not all, of the cases, and the only chance for the patient is in stopping the hemorrhage and removing the already effused blood. If the diagnosis can be made, laparotomy is justifiable, and would be the only resort. In the report by the French physician to the Obstetrical Society, no name is given, the patient is simply mentioned as an English actress.

KNOTTED UMBILICAL CORD.

DR. CLEEMANN exhibited for Dr. John A. Hunter an umbilical cord tied into a complete single knot. There was no difference in size of any portion of the cord and there had been no interference with the nutrition of the fœtus. Dr. Hunter had not been present at the birth of the child, but had come in soon afterwards, and in tying the cord and removing the placenta he noticed the knot. In a case reported by Dr. Wm. F. Jenks to this Society, a failure of the fœtal heart was noticed by auscultation, the child died in utero and the knot in the cord was suggested as a probable cause of the death of the fœtus. Such a knot as is seen in Dr. Hunter's case might be formed during parturition if a loop of the cord was around the child's neck and it was loosened and the body allowed to pass through it in the process of extraction.

DR. MONTGOMERY thought that such a knot, if existing in utero, might develop a murmur that could be discovered by auscultation.

ACUTE HYDRAMNIOS.

DR. E. E. MONTGOMERY remarked that although dropsy of the amnion is a quite frequent condition, that above named is exceedingly rare. For this reason he has felt that the following case was worthy of record. June 4, 1883, he saw Mrs. P., in consultation with Dr. Chase. She was pregnant for the fourth time. In the one preceding this she had miscarried. Her last menstruation occurred December 10, 1882. In her former pregnancies she had been quite small, carrying the fœtus low down. This time the abdomen was larger than formerly at the same period, but she continued without any special discomfort until one week ago, when, without any assignable cause, the abdomen began rapidly to increase in size, and continued to do so. The increase has been attended by pain, tenderness, difficulty in breathing, entire loss of sleep for three days, loss of appetite, and scanty flow of urine. She has been obliged to maintain a sitting posture, as lying down greatly increased the difficulty of breathing. They examined the urine, but found it free from albumen. The abdomen was distended more than we would expect to find it at full term. The tumor projected well forward and upward and a little more prominent to the right. It was perfectly regular in outline. The skin of the abdomen was smooth, tense, and glistening, and could not be pinched up over the tumor. It was quite tender to pressure. Short-waved fluctuation was distinct over the whole surface, percussion was dull, a slight tympanitic resonance could be determined in both inguinal regions. No part of the fœtus could be distinguished by abdominal palpation. In fact, all the external signs were those of an ovarian tumor. They imagined they heard the heart-sounds, but so indistinctly as to be uncertain. She said she had felt the fœtal movement for several days very slightly. Per vaginam the cervix was found dilated, the os open so as to admit two fingers to enter it. The vertex of a fœtus was felt presenting, and, singularly, was but slightly movable.

Considering the rapid enlargement in a few days, the extreme discomfort of the woman, as well as the imperilled circulation and the extreme improbability of the woman or fœtus surviving until the latter had reached a viable age, they concluded the best course was to induce premature labor, and from the urgent need of relief, to cause it by rupturing the membranes. This he did, and on the evening of the same day a stillborn fœtus was extracted. The upper part of the abdomen still continued almost as large as before. Examination per vaginam revealed the membranes of a second child. The rupture of these was followed by a gush and discharge of an enormous quantity of water. The second fœtus and the placenta were soon extracted. The latter was single with two cords. One cord appeared to have only a membranous attachment, but closer examination showed that it had been torn off from the base of the other cord. The quantity of liquor amnii was so great that it soaked through folded quilts, mattress, floor, and ceiling, and dripped upon the floor of the room below. The uterus contracted firmly and the patient was at once relieved. The children were both males, and well developed for the sixth month; the second child lived a few minutes.

The fixed position of a fœtus in the os in these cases has been given by McClintock as a sure indication of a plural pregnancy, but I must confess that this did not occur to me at the time, though I was unable to account for the anomaly. The existence of a single placenta in twin pregnancies is said always to be accompanied by children of like sex, this theory is here confirmed as far as is possible by one case. As to the cause of the condition authorities greatly differ. Gervis, in *St. Thomas Hospital Reports*, brings the causes under three heads: 1st. Cases due to inflammatory conditions of the amnion. 2d. Cases where the decidua has been found diseased and hypertrophied, but the amnion healthy. This will cause effusion into the

amnion by transudation owing to disturbed circulation. In these cases the fœtus suffers and may atrophy. 3d. It may arise from some maternal blood dyscrasia of uncertain nature, but evidencing itself by the same condition recurring in successive pregnancies in the same patient. Puerperal albuminuria may be the cause, and comes under this head. Simpson says disease of the placenta is likely to recur in the same individual. Savage asserts that an œdematous condition of the placenta is present in all cases of hydramnios. McClintock found a morbid condition of the placenta in every case. Mercier always attributed it to inflammation of the amnion. Others have ascribed it to obstruction of the fœtal portal circulation, or in the cord giving rise to transudation into the sac from the surface of the cord. Hydramnios greatly endangers the life of the fœtus. Of forty-three cases collected by McClintock, in which children were born where this condition existed, twenty were stillborn, sixteen of these had ceased to live for some days or weeks before labor, eleven of those born living died in a few days. Of thirty-three cases, four mothers died, showing a high maternal mortality.

In this patient the success of the treatment was greater than expected. As the distention had been so rapid, they feared loss of power in the walls of the uterus, and a consequent long first stage and liability to hemorrhage. It becomes an important question to decide whether they were justified in undertaking so promptly the induction of premature labor, but they felt that the probability of the death of the fœtus and the danger to the mother certainly in this case justified the procedure.

DR. B. F. BAER read the following

SUPPLEMENT TO THE PAPER ON THE EFFECT OF THE OPERATION FOR THE RESTORATION OF THE LACERATED CERVIX UTERI ON FERTILITY, CONFIRMATORY OF THE VIEWS THERE ADVANCED.

He there expressed the conviction, based upon his own experience, that sterility did not follow as a result of the operation, as had been asserted, but because the pathological conditions which almost constantly exist with the laceration were frequently not relieved, and this applied especially to the old cases. He there made this statement, "The longer the time which has elapsed between the occurrence of the injury and its repair (pregnancy being absent during this time), the greater and more permanent will be the changes in and about the uterus, which almost necessarily result in a continuance of the sterility after the cervix has been restored;" and he also said that if five years or more had expired between the occurrence of the injury and its repair, sterility would be likely to remain. In support of this, he reported twenty-seven cases, of which number thirteen had been sterile from six to sixteen years. Of this number, not one has become pregnant since the operation; but of the eight cases in which pregnancy had occurred within two to five years previous to the operation, he reported four that had become pregnant, and he now adds two more.

Case V.—Mrs. X., aged 32 years, mother of three children, youngest three years of age, complained of severe metrorrhagia every three weeks, and profuse leucorrhea in the intervals, together with a dull aching pain in the lumbar region and pelvis and a sharp spasmodic pain in the bladder, which caused an almost constant desire to micturate. She had lost weight, was anæmic and nervous, and had so many obscure aches and pains that the doctor took refuge in writing the words "general hyperæsthesia from nervous exhaustion." Physical examination showed the perineum to be lacerated to the external sphincter ani muscle, but not through it. The cervix uteri was torn bilaterally to the vaginal attachment, but not much hypertrophied. The body of the uterus was only slightly enlarged, but its cavity was relaxed and granular. On January 30, 1881, after four weeks' preparatory treatment, he operated on the cervix and secured a good result. He was made anxious on the second day after the operation by a rise of the temperature to 102°, which, however, subsided to the normal by the next day. This rise he ascribed to the use of the curette just before operating, which he now thinks ought not to have been done. This is the only instance in which he has observed a perceptible increase of temperature after this operation. This patient objected so strongly to the use of the catheter that he allowed her to pass her urine spontaneously. Since union was perfect here he allowed his next patient to do the same, with a like good result, and this has been his custom ever since. It was his purpose to restore the perineum, but she was so much benefited that she refused to permit it, and returned to her home in Michigan. A communication received a few weeks since informed him that she was spontaneously delivered at term six months ago.

Case VI.—Mrs. M., has had three children at term and one miscarriage, the latter two years previous to February, 1878, at which time she first consulted him. She complained of a dragging pain in the back from the sacrum to the nape of the neck, with menorrhagia and leucorrhœa. The neck and body of the uterus were hypertrophied, soft, and tender, and the former was badly torn on both sides; the mucous membrane was everted and abraded; sound entered four inches. February 17, 1880, he operated for the lacerated cervix; union was immediate. In his case-book, October 25, 1881: "This patient has been in excellent health since the operation; whereas, I had pursued the ordinary local treatment at intervals during two years before it, with only temporary improvement." She is now in the fifth month of gestation. This makes seventy-five per cent. of pregnancies following the operation of the eight cases of this class.

MEDICAL SOCIETY OF NEW JERSEY.

One Hundred and Seventeenth Annual Meeting, held at Atlantic City, June 12 and 13, 1883.

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, JUNE 12TH, FIRST DAY.

THE Medical Society of New Jersey met in annual convention at four o'clock, P. M., the PRESIDENT, JOHN W. SNOWDEN, M.D., of Waterford, in the Chair. The Vice-Presidents and other officers were in their respective seats.

The session was opened with prayer by the Rev. Joseph Garrison, of Camden.

There was an unusually large attendance of members, every District Society in the State except Sussex being represented by delegates. There were also present a large number of invited guests and corresponding delegates, among whom were Dr. Neal O. D. Park, from Rhode Island; Dr. Ed. C. Mann, from New York; and Drs. Henry Smith, Wm. B. Atkinson, W. H. Whitcomb, Hiram Corson, D. F. Woods, J. Solis Cohen, P. B. Walker, L. A. Duhring, W. Goodell, H. Leffman, and J. T. Eskridge, from Pennsylvania.

DR. BOARDMAN REED, in behalf of the Atlantic District Medical Society, and HIS HONOR CHARLES MAXWELL, Mayor of the city, addressed the Society, extending to it a cordial welcome to the hospitality of the district and city, and inviting the members of the Society and their families to participate in the excursion and banquet given by the citizens of Atlantic City.

REPORTS OF DELEGATES TO CORRESPONDING SOCIETIES were read by Drs. B. A. Watson and D. C. English, delegates to the American Medical Association, and W. W. L. Phillips, delegate to the Medical Society of Pennsylvania.

THE ANNUAL REPORT OF THE STANDING COMMITTEE was then read by the *Chairman*, DR. C. J. KIPP, of Newark. It portrayed the course and prevention of disease in the various parts of the State as reported by the district reporters. Throughout the State the prevalence of epidemics of zymotic disease is noted; scarlet fever, diphtheria, measles, pertussis, and mumps seem to have been universally present; scarlet fever and diphtheria often following each other closely in the same patient. Smallpox was reported in Trenton and Paterson. Pneumonia in epidemic form, and often fatal in character, was reported from several counties. Dysentery was epidemic in Essex and Middlesex. Reference was made to the interesting cases reported by members during the year.

The permanent establishment of the Society for the Relief of the Widows and Orphans of Medical Men of New Jersey was referred to. Also that free dispensaries had been opened in Jersey City, Trenton, and Paterson, and that hospital buildings had been erected in Orange, Elizabeth, and Plainfield.

The necrology of the year records the death of Drs. J. S. Payne, of Union County; J. W. Corson, Wm. Pierson, and A. W. Dougherty, of Essex; H. A. Hopper and K. K. King, of Bergen; J. W. Schenck and I. B. Mulford, of Camden; A. E. Budd, of Burlington; J. R. Leal, of Passaic, and C. L. Pearson, of Mercer.

REGISTRATION AT THE LATE MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

DR. E. M. HUNT, of Metuchen, introduced the following:

Whereas, The American Medical Association, at its late meeting, made new requisitions of delegates, before their names were allowed to be enrolled.

Resolved, That in nominating delegates to that body the Nominating Committee be requested to confer with our Committee on Ethics, and if they think necessary, with this Society, as to the propriety of this course and what action needs to be taken in reference thereto.

After considerable discussion the resolution was lost by a vote of ten in favor and thirty-two against it.

The following committees were then announced by the President:

NOMINATING COMMITTEE.

Atlantic, D. B. Ingersoll; *Bergen*, D. A. Currie; *Burlington*, T. T. Price; *Camden*, E. L. B. Godfrey; *Cumberland*, J. Ingram; *Essex*, D. S. Smith; *Gloucester*, G. C. Laws; *Hudson*, W. P. Watson; *Hunterdon*, O. H. Sproul; *Mercer*, W. S. Lalor; *Middlesex*, A. C. Hunt; *Monmouth*, J. E. Arrowsmith; *Morris*, J. G. Ryerson; *Passaic*, G. W. Terriberry; *Salem*, C. R. P. Fisher; *Union*, H. H. James; *Warren*, P. F. Hulshizer. Dr. H. H. James, Chairman.

EVENING SESSION.

The Society was called to order by VICE-PRESIDENT STEPHEN WICKES, of Orange.

THE PRESIDENT then delivered

THE ANNUAL ADDRESS,

which considered *The Aavances made in Medicine by Physical Diagnosis*. He gave a description of the different means of physical diagnosis, by whom and when introduced, and their mode of use and value to the diagnostician.

The thanks of the Society were voted to him for the address, and a copy requested for publication in the *Transactions*.

THE REPORT OF THE TREASURER showed the receipt of $1,094.54, and the disbursement of $589.43, leaving a balance on hand of $505.11; $2,100 are invested in U. S. Bonds. The Treasurer, Dr. W. W. Phillips, recommended the assessment for the year to be laid at $1.50 per capita.

The report was referred to Committee on Treasurer's Account.

The Committee subsequently reported as follows:

The Committee to whom was referred the report of the Treasurer, would respectfully represent that they have examined so much of his accounts as the absence of his books will admit, and find the balance-sheet presented correct. The Treasurer states that he has in his possession $2,100 in U. S. four per cent. bonds, deposited in Trenton. Your Committee would recommend that the Treasurer be required to give bonds to the amount of five thousand dollars for the faithful performance of his duty,

The Committee was continued, and instructed to carry out its recommendations.

DR. H. H. JAMES, of Rahway, presented the report of the Committee on

WHEN AND OF WHOM RELIABLE VACCINE VIRUS MAY BE OBTAINED,

in which he spoke of the difficulty of procuring good vaccine lymph, and especially of the unreliable virus which has been thrust on the professional community by the vaccine farms, vaccine companies, etc. The author believes that perfectly reliable virus may be obtained from Dr. Henry A. Martin & Son, Boston; Dr. Frank P. Foster, New York; Board of Health, Mott Street, New York.

DR. WRIGHTSON, of Newark, introduced the following:

Resolved, That a committee be appointed by this Society to confer with members of the State Legislature in reference to the enactment of a law by the State Legislature, which will provide for furnishing the medical profession in this State with pure bovine virus free.

The motion was lost.

WEDNESDAY, JUNE 13TH, SECOND DAY.

The Society was called to order by the President.

CONFERRING THE DEGREE OF M.D.

P. N. Jacobus, of Sussex, having presented an application for the degree of M.D., which was in accord with the by-laws, and a thesis, the subject of which was "Specialism and Fashion in Medicine," which was acceptable to the Society, it was voted that the degree be conferred, and the Secretary was instructed to issue a diploma to him.

DR. GEORGE BAYLIS, of Orange, read an essay on *Causes of Melancholia*.

The following were elected

OFFICERS FOR 1884:

President.—Stephen Wickes, of Orange.

Vice-Presidents.—P. C. Barker, of Morristown, Joseph Parrish, of Burlington, and C. J. Kipp, of Newark.

Corresponding Secretary.—William Elmer, Jr., of Trenton.

Recording Secretary.—William Pierson, of Orange.

Treasurer.—W. W. L. Phillips, of Trenton.

Standing Committee.—T. J. Smith, of Bridgeton; Samuel S. Clark, of Belvidere; E. J. Marsh, of Paterson.

DR. JOSEPH PARRISH, of Burlington, read a very interesting and instructive essay on

SOME PROBLEMS IN INSANITY.

He recommended medical inspection of county poor-houses, and the appointment of a lunacy commission, and referred to the increasing number of semi-insane people in the State, a large neurasthenic class which is in every physician's range of observation, and laid special stress upon the necessity of intermediate homes for such a class, where also convalescents may be placed as a preparation for a normal home-life. He urged the study of chronic cases, and believed that many such cases are susceptible of improvement. Many such have been under his own care. He related several such chronic cases, and read extracts from correspondence abroad confirming the views he had presented. The following resolutions were then unanimously adopted:

Whereas, The condition of the insane poor in the several county houses of the State is such as to warrant investigation by this Society, it is therefore

Resolved, That the President appoint a Committee on Lunacy, whose duty it shall be to visit the asylums and poorhouses in the several counties as often as may be suitable, and in a friendly and unofficial manner acquaint themselves with the condition of the insane, and report to this Society at its next meeting.

Resolved, That it is the opinion of this Society that a lunacy commission should be appointed by the State authorities as a means of protecting the pauper insane especially, and of improving the general condition of the almshouses of the State.

The following were appointed as members of the Committee: Joseph Parrish, of Burlington; E. J. Marsh, of Paterson; F. Gauntt, of Burlington; T. W. Oakey, of Elizabeth; William Pierson, of Orange.

HONORARY MEMBERS.

Dr. Thomas Addis Emmet, and Dr. Isaac E. Taylor, of New York, were proposed for honorary membership. The nominations, as required by the by-laws, were referred to the Committee on Honorary Membership, to report at the next annual meeting.

THE COMMITTEE ON PRIZE ESSAY

reported that no essays had been presented.

THE ARMY MEDICAL MUSEUM AND LIBRARY.

On the motion of Dr. E. M. Hunt, of Metuchen, the following were adopted:

Whereas, It is the opinion of the Medical Society of New Jersey, that the Army Medical Museum and the Library of the Surgeon-General's Office at Washington, D. C., have been largely instrumental in the advancement of sound professional and scientific knowledge, and that they give promise of still greater usefulness in the future; and

Whereas, It is learned with regret that both these collections are in great jeopardy from fire or accident through the insecurity and unsuitableness of the buildings, in which they are stored; it is

Resolved, That Congress at the coming session be respectfully urged to provide suitable indestructible quarters for these invaluable treasures, to secure them against any possible contingency of loss or damage.

Resolved, That it is the sense of this meeting, that the management of these national collections have been eminently successful in the past, and that any change of administration would not only be injurious to these interests, but would cast an undeserved stigma upon the Office of the Surgeon-General of the Army.

Resolved, That Congress be petitioned to provide suitable annual appropriations for the increase and preservation of the Museum and Library, and also for carrying on the invaluable Index Catalogue of the Library of the Surgeon-General's Office.

Drs. E. M. Hunt, B. A. Watson, and Wm. Wolverton, were appointed a committee to carry out the recommendation and the resolutions.

A paper

ON THE MANAGEMENT OF CASES OF IRITIS

was read by DR. C. J. KIPP, of Newark, of which the following is a brief abstract:

In the treatment of all cases of iritis, of whatever origin, the first indication is to secure dilatation of the pupil in order to prevent the formation of posterior synechiæ. For this purpose various mydriatics are used, the most reliable of which is the sulphate of atropine. In fresh cases five or six instillations of a few drops of a one per cent. solution of atropine, made at intervals of five minutes, will generally suffice to break up any adhesions that may already have formed, and produce full dilatation in the course of a few hours. If the atropine makes but little impression on the pupil, six to eight leeches should be applied to the temple. If leeches are contra-indicated a brisk cathartic will sometimes have the same effect. In some cases the action of atropine becomes developed after a Turkish bath. Warm fomentations to lids are of much service in all cases. In all severe cases the patient should be put to bed or at least kept in a darkened room until the severity of the disease is broken. After dilatation of the pupil is secured it should be maintained until all irritation has subsided. If the remedies already mentioned fail to produce a large pupil, mercurials should be given either by inunction or by the mouth. Salivation must be avoided. In some cases the muriate of pilocarpine will answer as well. Of late, he has been able to get along without mercury in most of his cases in which there were not marked symptoms of secondary syphilis. For the relief of the pain morphine is to be given in sufficient quantity to procure sleep at night. The hydrate of chloral will answer only in mild cases. In some cases, the repeated application of leeches to the temple will give more relief than anything else. The salicylates are also of much service, especially if symptoms of rheumatism are present. In other cases quinine will be of benefit. Paracentesis of the anterior chamber will give relief if the pain is due to increased tension of the globe, a symptom not at all uncommon in the so-called serous iritis. As long as the eye is at all irritable all close work should be strictly prohibited even if one eye only is affected, and in order to guard against relapses as much as possible only a very cautious use of the eye should be permitted for some months afterwards. If after the iritis has passed away, the pupil is excluded, that is, the entire pupillary margin fastened to the lens, an iridectomy should be made as soon as practicable. This operation is also recommended in cases in which the relapses are thought to be due to numerous and broad adhesions, although it does not always prevent relapses.

DR. E. C. MANN, of New York, read a paper entitled the

PATHOLOGY OF INEBRIETY,

in which he urged the importance of its early recognition and repression in its incipient stages. Inebriety is a disease where we have a most varied grouping of abnormal phenomena, traceable to altered action in the nervous system, and having for a starting-point some perverted functioning of one or more nerve-centres. It is a disease in which the victims are more or less irresponsible, as are the insane. It has a

curable, prodromic stage, a stage marked by various neurasthenic symptoms, which should be regarded as the danger-signal of active dipsomania not far off, although the irresistable craving for alcohol which constitutes the morbid condition of inebriety may not yet have been actively displayed. Electricity as central galvanization, and cerebral electrization, cod-liver oil with phosphates, etc., are indicated. Among the predisposing causes are heredity, the exigencies of American life, syphilis, the inheritance of a neurasthenic constitution. The fully developed disease exhibits great nervous irritability and restlessness, and there exists a departure from the healthy structure of the nervous apparatus, and it is this abnormal condition of the central nervous system demanding stimulants that constitutes the disease.

DR. DAVID WARMAN, of Trenton read a paper entitled

PROFESSIONAL FEES AND PROFESSIONAL HONOR,

in which the profession were urged to show their own respect for their calling by demanding from their patients just compensation. Frequent and early collections were advised, and the avoidance of the almost universally misplaced charity common to the profession, a charity that not only does not receive respect, but causes the profession to be held in contempt. Contracts with the various societies and mutual benefit associations were denounced. An appeal was made for a higher professional honor. The author portrayed the annoyances a medical man is exposed to in malpractice suits, and the injury done to true science by false claims of success in obscure cases; also the effect on public opinion of an ununited and quarrelling fraternity.

The Corresponding Secretary, Dr. Elmer, read several letters and telegrams of regrets of their inability to attend the meeting from honorary members and delegates from corresponding societies.

Dr. Leffman, one of the delegates from the Pennsylvania Medical Society, upon his presentation, appropriately responded in behalf of his colleagues.

DR. ELMER, in behalf of the committee appointed at the last annual meeting "to elaborate a plan for the putting into effect the suggestions made by the President in his address in regard to *the curriculum of medical study*," read an exhaustive report, which was referred to the Committee on Publication.

Dr. George T. Welch, of Keyport, was appointed *essayist* for the next annual meeting.

Cape May was agreed upon as the *place for the next annual meeting*, and the second Tuesday in June as the time.

It was voted that the assessment for the year be two dollars per caput.

The following were appointed the *Committee on Prize Essay:* Drs. John W. Snowden, E. M. Hunt, and B. A. Watson.

The subject of the essay to be "The Etiology and Pathology of Septicæmia and Pyæmia."

The following *Committee of Arrangements* for the next annual meeting was appointed: Drs. Harry Clark, H. G. Taylor, E. L. B. Godfrey, J. S. Whitaker, D. A. D. Allen, and H. Elmer.

STATE MEDICAL SOCIETY OF ARKANSAS.

Eighth Annual Session, held at Little Rock, May 30 and 31, 1883.

(Specially reported for THE MEDICAL NEWS.)

WEDNESDAY, MAY 30TH, FIRST DAY.

THE State Medical Society of Arkansas convened at 11 A.M., in the Hall of the House of Representatives, and was called to order by DR. CLAIBOURNE WATKINS, *Chairman of the Committee on Credentials*, who then introduced DR. J. H. SOUTHALL, PRESIDENT of the Society, who delivered the address of welcome: DR. J. H. SOUTHALL then delivered the

ANNUAL ADDRESS,

which was listended to with the closest attention.

The subjects discussed were: Organization and Perpetuation of County Medical Societies; Medical Legislation; The Relation of the Profession to Society and the Government; and Medical Education.

The Committee on Credentials reported the registration of thirty-two delegates and twenty permanent members.

The report of the Committee on Applications for Membership, showed that there were twenty-two applicants for membership in the Society.

AFTERNOON SESSION.

The Society was called to order at 2 P.M., by DR. TURNER, VICE-PRESIDENT.

DR. KELLER moved that the applicants against whom there were no protests be voted for, and the others be referred to the Judicial Council without debate. Adopted.

The following named physicians were balloted for and elected

PERMANENT MEMBERS

of the Society: Drs. J. J. Robertson, E. R. Dibrell, D. C. Carroll, S. M. Carrigan, H. L. B'Shers, J. B. Thompson, R. B. King, Leo E. Bennett, James A. Seaver, T. B. Hodges, L. L. Bond, F. G. McGavock, M. C. Weaver, R. C. Prewitt, C. C. Forbes, W. B. Barner, J. C. Wallis, A. P. George, J. W. Allen, A. J. Pulliam, J. M. Jenks, Chester Jennings.

Drs. J. A. Dibrell, Jr., A. N. Carrigan, W. W. Hipolite, Thomas W. Hurley, were appointed to fill vacancies upon the Judicial Council.

DR. J. E. BENNETT presented a paper on the *Radical Cure of Hernia*, with cases. He also read a paper entitled, *Traumatic Tetanus Successfully Treated by Fowler's Solution of Arsenic.*

DR. G. W. HUDSON, of Camden, read a paper on *Skin-grafting.*

DR. DIBRELL submitted an interesting paper on *A Case of Strangulated Inguinal Hernia in a Cryptorchid*, from lifting a heavy weight.

DR. R. G. JENNINGS read a paper entitled, *Ligation of the External Iliac Artery for Traumatic Aneurism of the Femoral.*

DR. C. S. KIRKSCEY read a volunteer paper entitled, *A Case of Osteo-sarcoma*, which terminated fatally.

DR. J. E. BENNETT presented a paper on *Radical Cure of Hernia on the Heatonian Plan*, which was read.

DR. KIRBY, of Harrison, read a volunteer paper entitled, *Notes of a Case of Placenta Prævia.*

EVENING SESSION.

The Society was called to order at 8.30 P.M. by the President.

THE SECRETARY read a letter from Dr. B. M. Hughes, of Eureka Springs, requesting his reinstatement in the Society. He had been expelled from the Washington County Society, which action was confirmed by the State Society at the last meeting. He had been guilty of publishing, in the secular press, reports of cures effected by himself with the mineral waters of the Springs, in violation of the Code of Ethics of the Society, and hence his expulsion. The communication was referred to the Judicial Council.

DR. E. CROSS, Chairman of the Committee on Gynæcology, read his report.

DR. J. T. JELKS read a paper on *Laceration of the Perineum*. He called attention to its danger and frequency. He showed the necessity of recognizing its presence, and explained the best processes for its treatment.

DR. W. H. HAWKINS, of Texarkana, read a paper upon *Puerperal Convulsions*.

DR. CARRIGAN read a short and interesting paper upon the same subject.

A paper by DR. DALE, upon an interesting experience in gynæcology, was read by Dr. Dibrell.

THURSDAY, MAY 31ST, SECOND DAY.

MORNING SESSION.

The Society was called to order at 9.30 o'clock.

The SECRETARY then announced the *Nominating Committee*.

The SECRETARY then read the following resolution, which had been introduced at the last meeting by Dr. Turner:

"*Resolved*, That section III of the constitution be so amended as to allow permanent members living in counties where there are no local societies, to have a voice in the Society, as well as delegates from subordinate societies."

DR. TURNER spoke at length in favor of the resolution.

DR. GIBSON opposed it, and gave many reasons for its rejection.

DR. KELLER thought that the resolution was right and proper.

It was opposed by Drs. Cross, Jennings, and Lenow.

DR. MCGAYOCK moved that the resolution be so amended as to allow one permanent member living in counties where there are not more than three graduates.

The motion to amend was adopted.

The amendment as amended was lost.

DR. HURLEY, Chairman of the Committee on Medical Education, submitted the report of the committee.

DR. JENNINGS, Chairman of the Committee on Medical Legislation, read the report of his committee.

DR. GIBSON, *ex-officio* Chairman of the Committee on Publication, read the committee's report,

DR. HIPOLITE read the report of the Board of Visitors to the *Arkansas Industrial University*, which was received.

AFTERNOON SESSION.

The Society was called to order at 2 o'clock by VICE-PRESIDENT TURNER.

The Nominating Committee reported the following as

OFFICERS FOR THE ENSUING YEAR:

President.—J. M. Keller, of Garland County.

Vice-Presidents.—G. W. Hudson, of Ouachite County; J. M. Carrigan, of Hempstead County; J. F. Blackburn, of Franklin County; D. S. Mills, of Jefferson County.

Secretary.—L. P. Gibson, of Pulaski County.

Assistant Secretary.—E. Meek, of Pulaski County.

Treasurer.—A. L. Breysacher, of Pulaski County.

Librarian.—John Waters, of Pulaski County.

Little Rock was decided upon as the

NEXT PLACE OF MEETING,

the time to be the Wednesday preceding the meeting of the American Medical Association in 1884.

DR. Z. ORTO, Chairman of the Committee on State Medicine, then read the report of the committee.

On motion, the reading of the report of the Committee on Necrology was omitted, and the same ordered to be prepared for publication.

SECRETARY L. P. GIBSON submitted his report, which was approved.

The Report of the Treasurer, DR. A. L. BREYSACHER, was submitted.

The report of DR. JOHN WATERS, Librarian, was also received.

The tender of the resignation of DR. PRICE was read and received.

The following resolution, introduced by Dr. J. E. Bennett, was then read by the Secretary:

Resolved, That a physician visiting the patient of a brother practitioner in an emergency should under no condition assume control of the case, except to meet the emergency, and that where circumstances arise where there is a doubt as to the proper course to be pursued, the physician should let the instincts of the gentleman be his guide, having in view alike his own honor and that of his profession.

DR. HAWKINS moved that the motion be laid on the table. Carried.

DR. CROSS then moved a reconsideration, which was carried.

DR. BENNETT moved the resolution be referred to the Judicial Council.

DR. HAWKINS considered that all contained in the resolution was covered by the Code of Ethics, and therefore he thought its discussion unnecessary.

DR. DUVAL contended that though the resolution might be covered in spirit by the Code of Ethics, it was not in letter, and he thought it a proper one.

The motion to refer prevailed.

DR. CROSS moved: *Be it resolved*, that Section 1, Article 9, in the Constitution, be so amended as to provide for a Standing Committee on Obstetrics. Laid over for one year.

Dr. Orto's resolution of the morning session was called up.

DR. BENNETT moved that it be referred to the Judicial Council.

On motion by DR. GIBSON, this motion was laid on the table.

Dr. Orto's resolution was then adopted.

THE CODE OF ETHICS.

DR. KELLER offered the following resolution:

Resolved, That the State Medical Society of Arkansas not only heartily condemns the effort of any local or State body of medical men to break down or destroy the Code of Ethics of the American Medical Association, but pledges itself to encourage no medical school or college whose professors, one or more, indorse or favor such effort.

The resolution was unanimously adopted.

DR. MILLS moved a reconsideration of the vote by which the resolution to amend the constitution was lost this morning. Carried.

DR. FOLSOM'S motion to amend the resolution by substituting "permanent members" for "graduates," was also carried.

DR. MCGAVOCK moved the adoption of the amendment as amended. Carried.

DR. HAWKINS moved that Dr. L. P. Gibson, as Secretary, be allowed an honorarium of $100. Carried.

DR. BRYSACHER moved to amend the constitution by decreasing the annual dues from $5 to $3. The motion went over for one year.

Dr. McGavock spoke in encouragement of the election to the Legislature of such delegates as would sustain a liberal medical law. He moved the President appoint a committee of five to address the medical men of the State and urge the importance of medical legislation. Carried.

Dr. Hipolite moved that Dr. Southall be appointed chairman of the committee. Carried.

On motion of Dr. Gibson, further consideration of the matter was postponed until after adjournment.

DR. BENNET then read a paper on *Diabetes Mellitus, with Cases.*

DR. T. E. MURRELL next read a paper entitled *Some Observations on Hydrobromate of Homatropine and on Jequirity.*

DR. W. W. HIPOLITE read a paper on the *Modus Operandi of Zymotic Influences.*

DR. G. B. MALONE read a paper on *The Influence of the Mind.*

DR. EDWIN BENTLY then presented a paper on *Observations on Concussion of the Spine from Falls, Blows, and Collision.*

DR. JELKS read a paper on *Hydrophobia and Laceration of the Cervix Uteri*, and DR. C. L. KIRK a *Report of a Case of Ascites.*

DR. SOUTHALL, the retiring PRESIDENT, in a few brief remarks, thanked the members for their universal kindness and appreciation of his efforts, and recommended their new officer to their kindest consideration.

DR. KELLER, in assuming the chair, said that owing to the lateness of the hour, he would make no long speech, but merely bow his thanks for this honor conferred upon him—the greatest honor of his life.

On motion, the Convention then adjourned.

In the evening a ball and banquet was tendered the Society by the local physicians.

NEW INVENTIONS.

A HEAD SUPPORT FOR THE LARYNGOSCOPIC MIRROR.

BY JULIAN J. CHISOLM, M.D.,

PROFESSOR OF EYE AND EAR DISEASES IN THE UNIVERSITY OF MARYLAND.

THE elastic rubber head-band, to which the laryngoscopic mirror is usually attached, is so very uncomfortable to me, when strapped around the head, that I never put it on without wishing that some one had devised a more convenient method for holding the reflector. For office work, Tobold's apparatus, with condensor and mirror attached, is all that one can desire, when gaslight is used. It is when a daylight

examination is made, or when consultations are required at the residences of patients, that one is compelled to make use of some portable device for holding the reflector, especially when both hands are needed for the manipulation of instruments. At such times, the elastic rubber head-strap has heretofore been the simplest form of support, but has many drawbacks, among which will be recognized especially the head constriction requisite for holding the mirror with the necessary degree of steadiness. I also find the mirror interfering materially with my eyeglasses, without which I cannot see clearly at short range. I have tried at sundry times to escape these annoyances by having the reflector attached to heavy spectacle frames, but with no success.

Some time since, I requested Mr. Willms, surgical instrument-maker of Baltimore, to prepare for me a broad steel band to run over the crest of the head from forehead to occiput, to one end of which the mirror would be secured. This steel band is about twelve inches long and one and a half broad. At either extremity is a crossbar of metal, well padded, three inches by one and a half inch. They make a firm support upon the head, and enable the spring to hold the mirror very securely. To the front of the broad spring are the nose supports and universal joint to which the mirror is attached. To render spectacles unnecessary, a small revolving wheel, containing four lenses, is secured to the back of the mirror. They are thirty-six, twenty, and ten-inch convex, with fifteen-inch concave. This combination of lenses can be thrown out of position, so as to leave the opening in the centre of the mirror free for those who need no aid in seeing.

This apparatus, when completed, with its three and a half-inch mirror, works very satisfactorily. It is rather odd that so simple a device had not long since been introduced. No one trying the metal spring, with its easy adjustment and comfortable wear, will ever bind again the head with the elastic rubber-band. The spring mirror-supporter can be put on the head with the greatest facility; will fit any head, and, with the lenses attached to the back of the mirror, as with the ophthalmoscope, will give clear vision to any eye with defective focusing.

A glance at the accompanying wood-cut will explain the great advantages which this simple apparatus exhibits over any other heretofore used by specialists for ear, nose, or throat explorations.

CORRESPONDENCE.

FRONTAL ELECTRIC PHOTOPHORE.

To the Editor of THE MEDICAL NEWS.

SIR: In the No. of your valuable journal for May 19th I notice a short account of a new instrument called by the long title of Frontal Electric Photopore, "recently invented" in France, for the purpose of illuminating the cavities of the mouth and nose by electricity. The same idea occurred to me some time ago, and last fall and winter I experimented with different lamps and batteries, which experiments were highly satisfactory, so that I inserted a short description of the apparatus in the second edition of my book on *Diseases of the Throat and Nose*, recently published. The form most convenient and satisfactory consisted of a small incandescent lamp, which was mounted on a separate arm attached to the head-band a little to one side and in front of the head reflector. The connecting wires were carried from the lamp along the hand to the back of the head, and from there down to the battery, thus being out of harm's way. The current was obtained from either a storage battery or from a bichromate of potash battery, the elements of which were combined for quantity. The light thus obtained was somewhat whiter than gas-light and of considerable penetrating power, and I found that the use of this electric head-light was far less fatiguing than when the head-mirror is used to reflect the light from a stationary gas-flame, because in the former case the light is always thrown forward in the direction of the axes of the eyes, and consequently the rays can be directed to any point without reference to position of the head.

I also used a small arc light, which on account of its whiteness and penetration would be preferable to the incandescent lamps, if a lamp could be made small enough to be easily managed. This I found, however, very difficult, and could not obtain an apparatus suited for the purpose, from any of the manufacturers, who make only lamps of 2000-candle power and upward, while 40 to 60-candle power is all that is desirable for laryngoscopic purposes.

Very truly yours,

C. Seiler, M.D.

Philadelphia, June 20, 1883.

NEWS ITEMS.

BROOKLYN.

(*From our Special Correspondent.*)

The Long Island College Hospital held its annual commencement last Tuesday at the Academy of Music, Andros P. Chesley being the valedictorian. The class of fifty-one graduates was passed out of sixty-five candidates. The address to the class was delivered by Chas. H. Hall, D.D. The Academy of Music was filled to the utmost by the friends of the graduating class and of the College.

A Hospital for Contagious Diseases.—There was some indication that a contagious disease hospital would be inaugurated in Brooklyn by the present Board of Estimate. That Board showed its disposition in regard to this measure of reform by putting $5000 in the budget for the purpose mentioned. But a difficulty has been discovered in the law, which fails to give authority to the Board of Health or any other municipal body to construct or carry on an institution of that kind.

The Vacant Coronership.—The recent death of Coroner John T. Parker throws the whole of the inquests of Kings County upon one man, Dr. F. Keller, there being only two coroners for the county. The vacancy will soon be filled by appointment by the Governor. One or more physicians are prominently named as the coming appointee.

TORONTO.

(*From our Special Correspondent.*)

The Proposed Medical College for Women has been duly organized, and the first session will open on the 1st of October next. The following form the Faculty as given in the announcement just issued:

Dr. M. Barrett, President and Lecturer on Institutes of Medicine; Dr. George Wright, Lecturer on Practice of Medicine; Dr. J. H. Cameron, Lecturer on Surgery; Dr. A. H. Wright, Obstetrics; Dr. A. McPhedran, Materia Medica and Therapeutics; Dr. J. T. Duncan, Anatomy; Dr. R. A. Reeve, Diseases of Eye and Ear; Dr. R. B. Nevitt, Sanitary Science; Dr. F. Kraus, Medical Jurisprudence; Dr. Augusta Stowe-Gullen, Demonstrator in Anatomy; A. R. Pyne, Esq., Lecturer in Chemistry.

The college is receiving the cordial support of the public, and many will contribute liberally to its endowment. It is worthy of remark that Dr. Stowe-Gullen is the only woman who has obtained a degree in medicine in Canada. She completed a full course of four years in Toronto, and graduated at the University of Victoria last month.

The Toronto Medical Society.—At the annual meeting of the Toronto Medical Society held in May, Dr. J. E. Graham was elected President, and Drs. Nevitt and Machell Vice-presidents, for the ensuing year.

LONDON.

(*From our Special Correspondent.*)

The Medical Societies.—London is now at its fullest, and all the festivities of the season in full swing. In accordance with this our medical societies have, with one exception, wound up their sessions and adjourned until October. The Clinical Society has had a very active session and in order to get through its work has had to hold an extra meeting.

The Debate on Diabetes.—The chief feature of the session of the Pathological Society this year has been a debate on diabetes, which demonstrated that nothing whatever is known of the morbid anatomy of that disease which can be regarded as of etiological import. Equally good observers find great changes and no changes at all in the nerve-centres of quite similar cases, and even Dr. Dickerson, the great apostle of capillary hemorrhages and vacuolations in the brain, admits that such changes are not constant. The discussion called forth, however, an able speech from Dr. Ralfe on diabetic coma, which has been already noticed in these columns, and a valuable contribution from Dr. Pavy, showing the importance of the study of this disease from its chemical side.

Nephrectomy.—At the last meeting of the Medical and Chirurgical Society, the subject of nephrectomy was discussed and Dr. Rawdon related a case in which he had excised a kidney for rupture with persistent severe hemorrhage. Cystotomy was subsequently performed for the relief of cystitis set up by retained blood-clot, and it appeared to have been this condition which led to the death from pyelitis and suppurative nephritis. The history of the case left the impression that earlier interference might have been attended with greater success.

The New Buildings of the Medical Society of London are just completed, and they will be formally opened at the annual soirée, at which the Prince of Wales is expected to be present. The President of the Society for the year is Sir Joseph Fayrer, who accompanied the Prince on his Indian tour.

The Attack upon the Medical Staff of the Army in Egypt.—A very strong feeling has been excited in the profession by the attack Lord Wolseley has made upon the medical officers who accompanied the army in Egypt. Lord Wolseley charges the surgeons with allowing their patients to suffer from want of proper food, beds, curtains, whisks, etc. In brief the reply is, 1st. That the patients did not thus suffer, and here the chief of the staff, who was in constant communication with the doctors, is in direct opposition to Lord Wolseley. 2d. That Lord Wolseley expressed at the time of his visits to the hospitals his hearty and complete approval of the way the sick and wounded were cared for, and even telegraphed home that the medical service was quite satisfactory. 3d. That he did not take any steps at the time to remedy what he now so bitterly complains of. The whole matter has been investigated by a committee, and Sir William MacCormack has done good service on the committee by his advocacy of the just claims of the surgeons. One of Lord Wolseley's complaints is that at one of his visits to the hospital at Tsmailia he could not distinguish the features of the patients, owing to the myriads of flies which had settled on them; but it is openly asserted that this visit was actually paid *at dusk*. Another charge he makes is that on a certain day the

patients at this hospital were lying on the floor without proper beds, and the actual fact is that there were three hundred patients in the hospital at this time, and of these two hundred and seventy were in beds. The other charges are equally reckless. At first Lord Wolseley's evidence made a great impression upon the public, but now opinion is coming round to see the facts in their true light. It is hoped that the matter will form the subject of a debate in the House of Commons.

THE MEDICAL BILL has passed the House of Lords, but at present has made no progress in the House of Commons, but is confidently expected to become a law before the end of the parliamentary session.

BERLIN.

(*From our Special Correspondent.*)

THE MICROCOCCUS OF ERYSIPELAS.—Modern surgery does not simply deal with mere practical questions, as is shown by the brilliant experiments of Fehleisen, one of Bergmann's assistants, who succeeded in breeding and isolating the micrococci of erysipelas in "pure cultures" (Reinculturen), after Koch's method. Remembering that erysipelas proves very seldom fatal when uncomplicated, and that this disease, on the contrary, sometimes acts as a resorbent in cases of morbid growths, he ventured to inoculate patients of that kind with such micrococci, and saw them taken with real erysipelas promptly after from fifteen to sixteen hours. This is the first instance of the reproduction of a human zymotic disease in other *human* individuals by the inoculation of isolated bacteria, the fatal qualities of the anthrax or tuberculous virus naturally forbidding similar experiments. This instance must convince even the most sceptical minds of the accuracy of the conclusions drawn from that well-known series of experiments inaugurated by R. Koch.

ROBERT KOCH.—There is no Berlin correspondence to-day which could avoid to mention the name of Robert Koch in one way or the other. Therefore, it may be of some interest for western readers to hear that this eminent man does not belong to the medical staff of some great hospital, or to the faculty of some celebrated university, but that he was a simple practitioner and State physician in Wollstein (a small provincial town not far from the Russian frontier) at the very moment when he finished his luminous experiments on the bacillus anthracis and on septicæmia in mice. Struck by the profound ingenuity and exactness of those experiments, Prof. Cohn, the well-known botanist of Breslau, in whose laboratory Koch had executed his first inquiries, made the proposition to him of coming over to this university; he did so, but failed to get an appointment, and, after a half year's waiting, he returned to his former residence. Perchance only a year later (in 1880), Professor Finkelnburg, of Bonn, resigned from the service as a privy councillor to the Imperial Board of Health (Reichsgesundheitamt) in Berlin, and Director Struck offered this post to the provincial practitioner. Once put in his element, Koch developed an admirable activity. He filled his laboratory with all instruments necessary for fruitful scientific researches on practical etiology, and began to work assiduously, but silently, until he went forth with one of the greatest discoveries of the century, viz., the plain and clear fact of a bacillus representing the active principle of the tuberculous process, which fact stands unshaken, even by the somewhat hazardous attacks of Spina, from the Vienna Pathological School. Dr. Koch is now at work gathering all clinical facts which may contribute to confirm his theory of the communicability of phthisis. Besides this, he and his able assistants are fully occupied by a vast series of experiments on the etiology of other infectious diseases; the influence of preventive inoculation, and the efficacy of disinfecting methods. The discovery of a bacillus belonging to farcy, made by Prof. Schütz and Dr. Löffler, may be mentioned as one of the most important results in the first direction.

THE CHENANGO COUNTY (N. Y.) MEDICAL SOCIETY AND THE NEW YORK CODE.—At the semi-annual meeting of the Chenango County Medical Society, held June 12, the following resolutions were unanimously adopted:

Whereas, The Code of Ethics adopted by the American Medical Association, in May of 1847, is the Code that has been adopted by all the State medical societies of the thirty-three different States, one territory, and the District of Columbia, and recognized by the profession generally, throughout the length and breadth of our land, as the Code of Ethics to control and regulate the medical profession in their intercourse with each other, their patients, and the public at large; and,

Whereas, This Code of Medical Ethics having been formerly adopted by our State Medical Society, and a departure made, without consultation with, or the sanction of, this National Association or any of the State medical societies with which we have stood, in mutual professional affiliation; therefore,

Resolved, That we, the members of the Chenango County Medical Society, of the State of New York, do hereby proclaim our adhesion to the Code of Ethics which we have heretofore adopted, being the same as the Code of Ethics of the National Medical Association; and that it is our deliberate and firm conviction and belief that its provisions and demands are the best and wisest known to us for the purpose of maintaining the dignity and honor of the profession, the highest good and welfare of our patients, and the best interests of the public at large.

Resolved, That we deem the American Medical Association as *the* proper source from which should emanate *any radical* change in the Medical Code of Ethics, and *its* authority paramount to *any* other known to us in our profession and as physicians.

Resolved, also, That we condemn the departure already made by our State Society, without consultation with, or approval of, the other State Societies with which we have heretofore, and desire still to be affiliated with; and, also, without the sanction of the National Medical Association, which has been the common bond of union of all the State societies and organized medical associations, as partaking too much of that spirit of secession which was once rife in our country, and which we cannot either, as patriots or physicians, sanction or approve.

THE NEW CODE.—*The New York Medical Journal*, June 2, 1883, says that "The attitude of the profession in the State of New York is one of voluntary renunciation—temporary, it is hoped—of certain present and material advantages for the sake of the ultimate triumph of a principle. New York acts not with an overweening idea of her own importance, but with a full appreciation that, in taking the stand she has taken, she entered upon a course of which every unpleasant consequence was foreseen and accepted as the necessary concomitant of the move she believed herself to be making in the interest of the whole American profession, and with confidence that the purity of her motives and the wisdom of her action will be acknowledged in the end."

THE MEDICAL SOCIETY OF LOUISVILLE effected a permanent organization last month, by the adoption of a constitution and the election of the following officers:

President.—Dr. Preston B. Scott.

Vice-Presidents.—Drs. L. P. Yandell and Coleman Rogers.

Secretary.—Dr. W. B. Doherty.

DIRECTORY OF MEDICAL SCHOOLS.—We learn that the Illinois State Board of Health is revising its "Directory of the Institutions Granting Medical Diplomas or Licenses in the United States and Canada." Copies of the last issue are being sent to the medical colleges, asking for corrections and additions, at the same time reminding the colleges that the schedule of "Minimum Requirements," as to the good standing of schools in that State, is now in force.

PROPOSED COLLECTIVE INVESTIGATION IN GERMANY.—At the meeting of the Berlin Verein für innere Medicin held on May 21st, Prof. Leyden submitted a report in which, after acknowledging the fact that the idea of collective investigation had been gained from the British Medical Association, are proposed the lines of an inquiry into phthisis on a far more extended plan than that undertaken recently in this country, which it may be remembered was limited solely to the question of contagion. The following subjects were formulated: 1st. The heredity of pulmonary phthisis, to include not only those who have inherited the disease, but also those members of a predisposed family who escape, with an enumeration of the age, sex, and special conditions under which the disease arises. 2d. The contagiousness of phthisis, as borne out by facts bearing on its communicability from husband to wife, and *vice versâ;* its spread in hospitals, workhouses, and prisons, through the medium of foul linen, clothing, dwellings, etc.; and from tuberculous animals, especially through their milk. 3d. The curability of phthisis, in which the histories of the cases are to be especially studied, with reference to diagnosis and the positive evidence of cure. 4th. The passage of genuine pneumonia, characterized by rusty sputum and a typical course, into true phthisis. These questions it is proposed to circulate widely among practitioners and medical societies, which will become centres of observation. The special circumstances of each patient are to be briefly recorded, together with an account of the course of the disease, of the physical examination of the lungs, and, as far as possible, the results of the examination of sputa for elastic fibres and bacilli, the method employed for the detection of the latter being stated. The collected returns will be finally analyzed by a committee. The report was to be discussed at the following meeting of the Society.—*The Lancet*, June 9, 1883.

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending June 9, 1883, indicate that pneumonia and inflammation of brain have increased, and that scarlet fever, tonsillitis, and mumps, decreased in area of prevalence.

Including reports by regular observers and by others, diphtheria was reported present during the week ending June 9, and since, at thirteen places; scarlet fever at twenty-one places, and measles at thirty-two places. Smallpox was reported in Lyons Township, Ionia County, June 6, and in Kalamazoo Township, Kalamazoo County, (five cases), June 10.

OÖPHORECTOMY IN AUSTRALIA—DR. ISAIAH DE ZOUCHE, Honorary Physician to the Dunedin Hospital, reports (*Australian Med. Journal*, Februry 15, 1883), with successful result, the first case of Battey's operation performed in the Southern Hemisphere.

HOME HOSPITAL FOR INDIA.—A new European hospital has been opened at Darjeeling, which is intended to serve the purpose of a sanitarium for Calcutta and the civil stations in Bengal, as well as to meet the wants of the Europeans resident in its immediate neighborhood. The institution has met with government support. It was recommended by the late Lieutenant-Governor, Sir Ashley Eden, who sanctioned a grant of 60,000 rupees.

CHAIR OF MEDICAL LOGIC AND JURISPRUDENCE IN THE UNIVERSITY OF ABERDEEN.—DR. OGSTON, Professor of Medical Jurisprudence in the University of Aberdeen, has intimated his intention of resigning the Chair of Medical Logic and Jurisprudence at the next meeting of the University Council. Prof. Ogston has filled this Chair since 1857, and has been a teacher of medical jurisprudence since 1838

OBITUARY RECORD.—*L'Imparziale* records the death of DR. CONSTANTINO FRANCESCONI, at the advanced age of seventy-three years, and who for forty-eight years has been in the practice of the profession.

———On May 15th, ROBERT DRUITT, M.D., F.R.C.P., F.R.C.S., in the 69th year of his age. He was one of the most active, best, and most widely known of English medical practitioners. Though obliged to retire from active practice in 1867, on account of ill-health, his deservedly popular writings have since that time kept him prominently before the profession. The first edition of the work by which he is best known, the *Surgeon's Vade-Mecum*, appeared in 1839, since which time ten editions have appeared, nearly 40,000 copies have been sold, it having been reprinted in the United States, and translated into several foreign languages. This and the article on "Inflammation" in *Cooper's Dictionary of Surgery* (1872), were his most valuable contributions to medical literature. Besides these he was the author of numerous pamphlets, addresses, and contributions to journals. During the ten years of 1862–1872, he was the editor of the *Medical Times and Gazette*. He was a man of rare scholarship, well-exercised judgment, and a comprehensiveness of mental grasp rarely equalled.

OFFICIAL LIST OF CHANGES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 11 TO JUNE 18, 1883.

TILTON, HENRY R., *Major and Surgeon.*—Granted leave of absence for four months.—*Par. 7, S. O. 136, A. G. O., June* 14, 1883.

APPEL, AARON H., *First Lieutenant and Assistant Surgeon.*—Relieved from duty in the Department of Dakota, and assigned to duty in the Department of the East.—*Par. 3, S. O. 130, A. G. O., June 7*, 1883.

POWELL, JUNIUS L., *First Lieutenant and Assistant Surgeon.*—Relieved from duty in the Department of Texas, and assigned to duty in the Department of the East.—*Par. 3, S. O. 130, A. G. O., June* 7, 1883.

RICHARD, CHARLES, *First Lieutenant and Assistant Surgeon.*—Relieved from duty in the Department of Dakota, and assigned to duty in the Department of the East.—*Par. 3, S. O. 130, A. G. O., June* 7, 1883.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL ARTICLES.

ON A METHOD OF POST-MORTEM EXAMINATION OF THE THORACIC AND ABDOMINAL VISCERA

THROUGH VAGINA, PERINEUM, AND RECTUM, AND WITHOUT INCISION OF THE ABDOMINAL PARIETES.

BY HOWARD A. KELLY, M.D.,

RESIDENT PHYSICIAN AT THE EPISCOPAL HOSPITAL, PHILADELPHIA.

IT is often a source of great disappointment to physicians to be unable to secure autopsies in obscure cases, on account of the unwillingness of relations and friends to permit any "mutilation" of the body.

In a large proportion of such cases the difficulty may be met, and a satisfactory autopsy secured by the method described in this paper, which I have now practised in five cases.

A post-mortem was very desirable in the case of a powerful Irishman aged thirty-two years, who died in the Episcopal Hospital of right apex pneumonia. His friends, however, were of that class who never consent to any disturbance of the remains for purposes medical or scientific, so I could only make the requisite examination on condition that I should not make any visible mutilation of the body.

The rigor mortis was extreme, rendering it impossible to flex the legs into the lithotomy position with the help of a strong assistant, so they were drawn apart to an angle of about sixty degrees and held in an elevated posture by bandaging to a long gas-pipe over the table.

Drawing the scrotum up, I made an incision from the perineo-scrotal junction to the margin of the anus and down to the bulb. Then cutting around this, and carrying the knife through the subjacent tissue up to the pelvic fascia underlying the vesico-rectal pouch, without injuring either bladder or rectum, the left hand was forced in, and gradually worked up through the pelvic into the abdominal cavity, between the parietal peritoneum and the recti muscles.

Breaking through the peritoneum, the hand was immediately invested on all sides by intestines, which clung to it, fitting like a tight glove, and following every movement with an indescribable sensation of suction, most impressively demonstrating the compact relations and mutual adaptability of the viscera.

Pushing the arm, bared to the shoulder, steadily upwards the free border of the liver was reached, and that organ depressed. An unsuccessful attempt was made to perforate the diaphragm with the fingers. The arm was withdrawn, and again introduced carrying up a scalpel with its blade flat against the index finger. The diaphragm nicked and the knife withdrawn, a large rent was easily made, and the hand passed into the right pleural cavity. The condition of the whole lung was ascertained by touch. The lower lobe was soft and crepitant. Some large, fatty-looking, infiltrated shreds of lymph were torn from its pleural surface and removed. The upper lobe was solid and denser than the friable liver. Adhesions similar to those below existed everywhere over the apex, but were readily detached, and masses of the same kind of lymph brought down.

The whole right lung was dragged partly into the abdomen, when the knife was again needed to sever the bronchus and the vessels at its root, after which it was removed from the body in two perfect parts. The lower lobe coming first, slipped down into and out of the pelvis without any trouble.

The consolidated upper lobe offered considerable resistance at the superior pelvic strait. It finally engaged and was slowly expelled intact by combined traction through the perineal incision and expression through the lax abdominal walls. It fell with a thud to the floor, looking more like a liver as it lay, of a dark-red color and convexity up.

On section it presented the appearances characteristic of pneumonic tissue passing from the second to the third stage.

The right kidney was removed, and found to be enlarged and greatly congested.

Upon the completion of the autopsy some wads of oakum were pushed up into the abdominal cavity, and the perineal incision carefully closed by sutures, and upon returning the body to its proper position not the slightest trace of the examination remained visible.

This man was five feet nine inches in height, and measured twenty-nine inches from top of sternum to perineum over the surface of the body.

The difficulties encountered were probably as great as any to be met ordinarily in removing thoracic viscera through the pelvis. With my hand in the cavity I could easily touch the first intercostal spaces and examine the whole interior of the chest.

The heart can be removed in the same way, and if necessary a short-bladed, long-shanked knife can be introduced subcutaneously to divide the great vessels at its base.

Of the abdominal viscera, the intestines, spleen, pancreas, and kidneys can be taken away without difficulty, the liver must ordinarily be divided.

My hand when squeezed up, with the fingers elongated, measures seven and a half inches in circumference, my forearm eight and a half, and the arm nine inches. It would hardly be possible for an arm exceeding these measurements by two inches to make a post-mortem on an average subject in in this manner. The arm is frequently obliged to rest, temporarily paralyzed by the constrained posi-

tion, and by the pressure made on the muscles by the sharp angle at the superior pelvic strait, and the strong suction made by all the surrounding structures when traction is made on any viscus.

This last difficulty is a serious one, and it would be much better to obviate it by making a puncture and introducing a small tube to allow free access of air.

This method of securing an autopsy can be practised with slight modification and to still greater advantage, in regard to neatness and perfect concealment, upon the female, as in the following case:

M. O'H., a fine-looking, well-formed Irish girl of twenty-two, living in a large inland town, was brought to the hospital in a condition of extreme anasarca, from which she shortly afterwards died.

On account of the objections urged by her friends, it was determined to make the examination, if possible, without leaving any external trace of it. Bringing the body down to the end of the table and separating the legs as far as possible, the vagina was well syringed, and then, with two fingers of the left hand guiding the knife in the right, an incision was made in the right fornix, through the vaginal wall close to the os uteri. Pushing in the whole left hand and forcing it through the rent, the abdominal cavity was readily reached and the contents examined.

The right kidney, which proved to be a large white kidney weighing eight ounces, was slowly loosened from its attachments and dragged down, frequent pauses being necessary to allow the arm to regain strength. The use of the knife was not necessary in this post-mortem, which was performed before the one above described.

After taking out the left kidney, which presented the same appearance, the vagina was packed with cotton and the body replaced in the coffin, bearing no marks which could suggest a disturbance of the remains.

In the case of G. W., a man twenty years of age, who died in the ward in consequence of large pleuritic effusion and complete splenization of the right lung, and the same condition partially advanced in the left, and marked pericarditis, I made an autopsy of the thoracic viscera per rectum, hoping in this way to make as neat and complete an examination as that in the woman per vaginam.

After giving the gut a thorough washing out, the hand was pushed in, expending considerable force in the gradual dilatation of the sphincters, and the rectal pouch cut through posteriorly. The hand was pushed through this incision and up the hollow and over the promontory of the sacrum into the abdomen. Breaking through the peritoneum, the liver was depressed and the thorax reached and examined as in the first case, and the specimens removed.

The anus was left as large as my arm and gaping, a far more conspicuous object than the closed perineal wound well concealed by the legs and scrotum.

A METHOD PROPOSED TO SECURE CHILDREN AGAINST ATTACKS OF DIPHTHERIA.

By F. PEYRE PORCHER, M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA, CHARLESTON.

(*Read before the South Carolina Medical Association April, 1883.*)

IN the course of a review published in the *Charleston Medical Journal* many years since, in a letter to a medical gentleman in Philadelphia written in 1878, which appeared in a medical journal in that city, and which was copied in the *Medical Brief* of Missouri, the prescription it contained being also reprinted in *Naphey's Therapeutics*, first edition, I submitted a plan for *preventing* the attacks of this fatal disease. The measures recommended were to be used by those who were well, but exposed to its contagion. My ideas were based upon the fact that diphtheria at its inceptive stage is local, and generally has its seat upon the fauces, which, if acted on and modified by suitable agents, would not offer a nidus for its reception. If micro-organisms are the agents by which diphtheria is caused or propagated, then they will be less likely to effect a lodgement upon surfaces which are subjected to the repeated action of remedies which, whilst uninjurious, may also prove efficient in the destruction of such organisms. I also selected agents well known for their activity and value as tonics, depurants, and antiseptics, which would be adapted to the treatment of the disease should our efforts at prevention prove abortive.

The prescription is as follows, the alcohol being a comparatively recent addition:

R.—Chlorate of potash,	.	1 to 2 drachms.
Mur. tinct. of iron,	.	2 to 3 drachms.
Quinine, . . .	.	15 to 20 grains.
Hyposulphite of soda,	.	1 to 2 drachms.
Alcohol, . . .	.	1 to 2 ounces.
Water, ...		6 ounces.—M.

S.—A teaspoon to a desertspoonful, in a little water, to be used two or three times a day by those *exposed* to the contagion.

I have directed and used this combination for years past in many families here, by whom it has always been kept; upon my recommendation it has been given elsewhere; and though the testimony must always be negative, I have never known a case of diphtheria to occur where it was employed. The experience of one physician, however, cannot be conclusive upon such a subject, and others must examine into the merits of a claim of such importance.

In the early part of the past year in a communication, made at his request, to my friend, Dr. Thomas F. Wood, editor of the *North Carolina Medical Journal*, I suggested that an addition might be made to the above formula in the case of children much exposed to the dangers of infection; when, for example, the disease existed or had recently occurred in a household. This consisted in the addition to each dose of one-fiftieth to one-seventy-fifth of a grain of the bichloride of mercury, and it was based upon the special power of this agent in its action on micro-organisms as an antiseptic, germicide and parasiticide.

In the recent paper by Dr. Sternberg (*American Journal of the Medical Sciences*, for April, 1883), entitled "Experiments to Determine the Germicide Value of Certain Therapeutic Agents," the highest rank is given to the bichloride of mercury as a germicide, iodine being next in order; and he states as a confirmatory fact that they are now using it in Vienna as a remedy in diphtheria. Dr. James C. Wilson, of Philadelphia, in an article in the same issue, recommends it as a potent disinfectant for the stools of enteric fever. Dr. R. F. Weir, in an article published in The Medical News for May 5, 1883, has also referred to the probable value of corrosive sublimate, given internally, in germ diseases. These observations only confirm the value of the suggestion I had long since made with regard to the use of this agent. The employment with similar intent of thymol, salicylic acid, eucalyptus, the oils of gaultheria and mint, or the combination known as "Listerine," may prove useful; but I do not think that principles derived from vegetables will modify mucous surfaces or the blood as powerfully as those from mineral.

If diphtheria be so great a scourge, and the combination I propose be not hurtful but beneficial—even if regarded simply as a tonic and roborant—if there is even a probability that it will prevent attacks, then I hope that the profession will test the efficacy of this formula. If my anticipation becomes realized by the observations of others, then such uninjurious agents, as were advised in the original prescription will not be withheld even from the laity, but will be widely disseminated.

In conclusion, I would add that I have found it serviceable likewise in scarlet fever, and, with the substitution of two or three drachms of supertartrate of potash for the hyposulphite of soda, it has proved in my hands extremely useful in erysipelas, in cellulitis, and diseases of the lymphatic system where there are swelling and puffiness of the subcutaneous cellular tissues.

MEDICAL PROGRESS.

Action of Lead on the Stomach and Intestines.—Rudolph Maier draws the following conclusions from experiments which he made on this subject: Rabbits and guinea-pigs died from lead-poisoning with doses of grs. iij, daily in from ten to two hundred and twenty-six days. In all of them marked changes were observed in the stomach and intestine. There occurred first, turbidity and fatty degeneration of the gland-cells; second, dilatation of the arteries, venous congestion, hemorrhages and circumscribed brown softening; third, increase in the submucous connective tissue, and sclerotic degeneration of the submucous and mesenteric ganglia. The changes in these latter give rise to lead colic. The changes in the intestine explain the emaciation of the animals. The author considers himself justified in drawing general conclusions regarding chronic lead-poisoning from his experiments, and in defining the condition as parenchymatous degeneration with consequent induration of the connective tissue, similar to chronic phosphorous poisoning, and the symptoms are those of chronic hemorrhagic inflammation, and of a neurosis affecting the most diverse parts of the nervous system.—*Practitioner*, June, 1883.

Instrument for Dilating the Cervix by Elastic Pressure.—Dr. E. T. Williams recently presented such an instrument to the Boston Society for Medical Improvement. It consists of a soft rubber bulb and flexible tube, a pair of compressing splints, and an elastic rubber band. The bulb, being filled with water, is to be connected with a Barnes' bag or any other water dilator. This being inserted into the cervix, compression is to be applied to the bulb by means of the splints and elastic band, and the instrument left in position to do its own work. Compression can be graduated to fit the circumstances of the case.

The means of connecting the Barnes' bag with the tube from the bulb, is by a screw on the tube, fitted to hold the small nozzle of a Davidson's syringe, which nozzle is to be slipped into the tube of the dilator and securely tied in.

Connection can also be made with Emmet's dilator. The upper part of the instrument being carried beyond the os internum, necessarily bulges into the cavity of the womb, thus forming a sort of head, like the head of a nail, which keeps the dilator from slipping out. No portion of the bag should be permitted to protrude below the external os, for if this happens, bulging will occur at this point and tend to draw the dilator out of the uterus. The same thing happens with sponge tents if not cut off even with the os. The chief defect in Emmet's instrument is the insecurity of the button-clamp by which the bag is secured to the tube, which will not stand the necessary amount of pressure.

He also showed a substitute for Emmet's instrument, consisting of a flexible rubber tube with a perforated wooden spool-shaped tip, and over the tip two rubber finger-cots secured with twine. The inner cot is intact and intended to be filled with water; the outer had a hole for the introduction of a sound, which, being pushed up between them, serves to introduce the instrument into the uterus. This takes the place of the "sleeve" of Emmet's dilator. The sound can be removed when the bags became fully engaged. The objection to all these instruments is their bulk, which prevents their use except when some dilatation exists already.

For the normal non-pregnant os, he showed a metallic intra-uterine syringe tube, with a screw to fit the bulb tube already described. Over the end of the silver tube a rubber cot was tied. A slight swelling of the tube, two and a half inches from the end, would keep the cots from slipping off. Some small clots, made for the speaker, were shown, having a diameter of a quarter, a third, and a half inch. These may be inserted like a sponge tent. The tendency to slip out of the uterus can probably be prevented by packing the vagina or by tying in the syringe tube like a catheter.—*Boston Medical and Surgical Journal*, June 7, 1883.

Effect of Drugs on Hæmaglobin.—An investigation on this subject has led Fenoglio to the following results: Preparations of iron have a very unequal action, and during their administration the quantity of hæmaglobin in the blood should always be tested. Lactate of iron and Bland's pills (consisting of oxide of iron and carbonate of potash) are preferable to Bravais' dialyzed iron; but though this preparation is not so powerful as the others, it is by no means without effect. The action of Fowler's solution becomes more powerful the longer it is continued. Notwithstanding the opposition of many authors, Fowler's solution is indicated in anæmia and chlorosis, and all conditions where the hæmaglobin of the blood is diminished, for this preparation both increases the hæmaglobin and improves the appetite and the general appearance.—*Practitioner*, June, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, JUNE 30, 1883.

BACILLUS NOTES.

IT is evident from recent studies, that methods of treatment have much to do with success or failure in the demonstration of these organisms in tubercular tissues. It will be remembered that both Koch and Ehrlich asserted that tubercle-bacilli are stained by alkaline solutions of certain aniline colors, but that they are impermeable to acids and certain brown colors, as Bismarck-brown and vesuvin, and that therefore they are not stainable by the former and cannot be decolorized by the action of the latter.

Recently, however, not only Spina, but Lichtheim, Ziehl, Finkler, and Eichler have controverted these views. Spina, Lichtheim, and Ziehl have shown that the staining solutions need not necessarily possess an alkaline reaction. Spina, Ziehl, Finkler, and Eichler have shown that nitric acid penetrates the bacilli; and Spina, Finkler, and Eichler have all noted the staining of bacilli by the brown coloring matters.

Recently, at the invitation of Prof. Stricker, Drs. Kaberhel and Matray have repeated Spina's experiments, and have shown that all solutions of methyl-violet and methyl-blue, whether alkaline or acid, stain the bacilli; and have further observed that the stained tubercle-bacilli are decolorized by nitric acid; while Kaberhel has also shown that tubercle-bacilli may be stained in solutions of brown coloring matter, and Matray has treated tubercle-bacilli with a mixture of acidulated solutions of fuchsin and vesuvin, with the effect of staining many of them, although Koch and Ehrlich have denied that staining would take place under such circumstances.

So, also, Dr. Lawrason, of New Orleans, who has been working in Philadelphia upon this subject for some months, has shown that the effect of a too prolonged treatment by nitric acid is to remove all the color from the bacilli and to render many of them invisible. We have recently examined some exquisite examples of sections made by this gentleman, of tuberculosis of the lungs and lymphatic glands, in which aggregations of stained bacilli quite large enough to be seen by the naked eye are present, resolvable by the microscope, aided by an achromatic condenser, into collections of typical *bacilli tuberculosis*. The sections were treated by saturated watery solutions of aniline oil, 100 parts, and saturated alcoholic solution of fuchsin, 11 parts, and then placed in a solution of one-third formic acid and two-thirds water for two hours. The sections were then thoroughly washed in absolute alcohol, cleared up with oil of cloves and mounted. He informs us emphatically that the effect of prolonged immersion in solutions of nitric acid is to decolorize the bacilli and to make them invisible.

Finally, by pursuing Koch's method Dr. Matray has succeeded in staining blue upon a dark ground, rod bacteria, isolated cocci, cocci in pairs and in colonies as well as leptothrix and torula forms of bacteria. These have been found in bronchiectatic sputum, in that of bronchial asthma, and diffuse bronchitis, in the coating of the tongue of non-phthisical individuals, lochia of a non-phthisical lying-in woman, in the sputum of pneumonia, in the stools of typhus patients, and in the fluid expressed from the tissues of a man dead of malignant œdema. He also found from the same sources and localities, except the last, bacilli exactly similar in form and size, grouping, and reactions to the so-called tubercle-bacilli of Koch.

At the conclusion of an article in the *Wiener medizinische Presse* for May 13th, Dr. Arnold Spina justly claims that these facts confirm the conclusions arrived at in his original studies, viz., that other cleft fungi behave precisely towards staining agents as do the bacilli of Koch, while the latter also deport themselves towards staining fluids as other bacteria. Not only this, but they lead us to expect the constant occurrence of bacilli in the organs of the body, and such an assertion is indeed made by Dr. Gärtner, of Vienna, who promises later to publish detailed results.

IN striking contrast with the above, we formulate from the results of a recent study of 380 cases of pulmonary phthisis by Fräntzel (*Deut. med. Wochenschr.*, for April 25th), the following conclusions:

1. Whenever tubercle-bacilli are found in the

expectoration there must exist tuberculosis of the lungs.

2. On the other hand, where the expectoration from pulmonary disease, nothwithstanding repeated and careful investigations, contains no tubercle bacilli—provided always the sputum is from the lungs and not the upper air-passages—there is no pulmonary tuberculosis, or there are at least no softening foci discharging into the bronchi.

3. The more abundant the bacilli in the sputum, the graver the prognosis.

4. If during the observation of a case extending over a sufficiently long time, the bacilli in the expectoration become sparser and sparser, we may infer at least a cessation of the softening process.

DR. PAUL GUTTMANN has recently (*Deut. med. Wochenschr.*, May 23d) found the *bacillus tuberculosis* in two cases of tubercular ulcer of the soft palate. This rare affection, including tuberculosis of adjacent parts, hard palate, root of the tongue, and pharynx—collectively known as pharyngeal tuberculosis—occurs, in his experience, in about one per cent. of cases of phthisis. Beginning in characteristic pin-head sized miliary tubercles, these quickly cascate in from two to three weeks, and the confluent tubercles break down into tubercular lintel-sized ulcers, which again unite to form somewhat larger ulcers.

The bacilli were found in enormous numbers in the secretion scraped from the surface of the ulcers and treated in the usual manner—in the one instance before the patient's death, and in the second, afterwards. In the latter they were also found in thin sections through the soft palate, but they were not numerous.

Since tuberculosis of the soft palate is always secondary, and only occurs late in phthisis, Guttman is inclined to believe it is the result of inoculation by the bacilli in the expectorated phthisical sputa adhering to the soft parts. Such adhesion and inoculation are of course facilitated by excoriation of the epithelium.

THE ACTION OF REMEDIES ON THE CEREBRAL CORTEX.

ALBERTONI, in vol. 15 of the *Archiv für experimentelle Pathologie und Pharmacologie*, has published the results of a research on the action of medicaments affecting the cortical centres. He has pursued a novel method. Referring to the experiments of Hitzig and Fritsche, of Ferrier, of Nothnagel, and others, who had by electrical excitation mapped out certain motor areas in the cerebral cortex, Albertoni proposed to himself to utilize this method for ascertaining the effects of remedies on the cerebrum. It has been ascertained that on feeble electrical excitation of certain convolutions, muscular movements follow, and that more decided stimulation will induce attacks of a distinctly epileptiform character. Hughlings Jackson had previously shown that irritation of the cortex by a "coarse lesion" caused epileptic seizures. Albertoni proposed to excite, in a similar way, epileptic attacks in animals, and ascertain the effects of remedies in preventing them, or diminishing their violence, if any drugs possess such powers. The research was carried on in Schmiedeberg's laboratory, at Strasbourg, and was limited to bromide of potassium, atropine, and cinchonidine.

The general belief in the value of the bromides as remedies for epileptic and epileptiform seizures is confirmed by Albertoni's experiments. He found that bromide of potassium possesses in a marked degree the power to allay the excitability of the brain, and this effect is the more conspicuous the longer the remedy has been administered and the more decidedly the system is affected by it. Indeed, a condition of the brain is ultimately attained in which no amount of electrical excitation will induce convulsions.

As might have been *a priori* expected, atropine did not exhibit similar properties. It seems to increase rather than lessen the excitability of the cerebrum. It had no power to affect the results of electrical excitation, and did not lessen the action of the weakest current sufficient to induce movements. This result also corresponds to the clinical experience of the medical profession—for belladonna has not proved useful in epilepsy; notwithstanding, Trousseau rated it comparatively high in the days before the bromides were introduced.

ACETONURIA AND DIACETURIA.

RECENT studies have contributed considerably to our knowledge of these processes, which were formerly considered to be peculiar to diabetes, and to cause the so-called diabetic coma. Thus, in a late paper (*Deut. med. Woch.*, May 23d) JACKSCH asserts that the phenomena of diabetic coma, so-called, occur also in carcinoma and the infectious diseases, and are attended by the presence of acetic acid in the blood. Whence the condition of the urine is termed *diaceturia*, in contrast to *acetonuria* a much less dangerous condition which constantly attends high grades of continuous fever. Naturally, also, the term *coma diaceticum* is preferred for the more serious condition to the older *coma diabeticum*.

Jacksch adopts the view of Frerichs, that the state of the blood is due to a zymotic process, the exact nature of which is as yet unknown.

KISSING—A DANGER.

AT first sight, it might be doubted whether this subject belongs to a medical journal. It needs no science to practise it, to enjoy it, or to be annoyed

by it. It might well be ignored by us, were it not that there is *danger* in it.

The annoyance to children of being urged, and often even compelled, to kiss visitors and strangers is bad enough, but there is also a serious danger in the habit, since it is not a very infrequent source of most loathsome contagion.

One of the commonest secondary results of syphilis is mucous patches in the mouth. Glass-blowers, who pass the glass from mouth to mouth at their trade, frequently suffer from syphilis caught in this way. One of the most terrible cases ever published occurred in this city some years ago, in which over one hundred persons were infected with syphilis by an itinerant tattooer, who moistened his India-ink with his saliva.

Syphilitics who have mucous patches invariably should be warned against kissing others, and especially any member of their families, lest they infect them. Children should not be allowed to put into their mouths toys vended on the streets, and constantly used by the vender and other persons. The danger of infection from using tincups or tumblers in public places is also a real one, though much less so than those above alluded to, since the virus is apt to be washed away. But such cups should always be carefully rinsed before being used.

The same danger exists in diphtheria, and in all cases of this disease the members of the family should not kiss the patient. Neglect of this rule claimed in the late Princess Alice a conspicuous victim, mourned by two kingdoms.

WE note that the itinerant Hale, to whose career in Wheeling, W. Va., we alluded in a recent issue, has been arrested in Toledo, O., on a charge of circulating obscene literature, which appeared in the journal *Health and Home*. He is to be promptly tried, and it is hoped he will be summarily and severely punished. His offences are practically of the same character as those charged against the abortionist Hathaway, who could never have plied his revolting trade in Philadelphia, had there been in Pennsylvania such a registration law as exists in Illinois and West Virginia, and has recently been enacted in the State of Wisconsin.

SOCIETY PROCEEDINGS.

AMERICAN NEUROLOGICAL ASSOCIATION.

Ninth Annual Meeting, held in New York, June 21, 22, and 23, 1883.

(Specially reported for THE MEDICAL NEWS.)

THE ninth annual meeting of the American Neurological Association was held in New York, in the Hall of the Academy of Medicine, on the 20th, 21st, and 22d of June. Sessions were held, on the afternoon and evening of the 20th and 22d, and on the afternoon of the 21st, the evening of that day being set apart to a dinner, given by Dr. Amidon, of New York, to the President, Dr. Edes, and to a reception to the members of the Association by Dr. Morton, at his residence.

WEDNESDAY, JUNE 20TH, FIRST DAY.
AFTERNOON SESSION.

ADDRESS OF THE RETIRING PRESIDENT.

DR. WILLIAM A. HAMMOND, the retiring *President*, in calling the Association to order, referred to the fact that many of the papers read before the Association last year had been reprinted in Europe, and some of them, either in whole or in part, in most of the languages of Europe. He said that great interest was being manifested in neurological medicine in this country, although not so much, perhaps, as the subject merits. He was somewhat at a loss to know why it was that certain other societies devoted to special branches of medicine were largely attended, while this body, working in a field of greater importance than all the others combined, had comparatively small attendance, unless it were that perhaps every one regards himself as something of a neurologist, and that the limits of the subject were not so well defined as the others mentioned. He then introduced the incoming President, Dr. Edes, of Boston.

The PRESIDENT, DR. ROBERT T. EDES, then delivered

THE ANNUAL ADDRESS,

in which he briefly reviewed the progress of neurology during the past year, referring particularly to the better knowledge of analysis as the means of locating disease; much, however, being lacking in essential knowledge of disease, a great deal of so-called knowledge of neurology is merely speculative, and especially with reference to the beginning of nervous diseases.

The PRESIDENT then read a note from Dr. Seguin, of New York, now in Europe, explaining his absence and expressing his interest in the work of the Association.

The minutes of the Association's proceedings of last year being already in printed form and in the hands of the members, their reading was dispensed with.

ELECTION OF MEMBERS.

Upon the favorable report of the Council the following candidates for membership were elected by ballot: Leonard E. Weber, M.D., of New York; G. L. Walton, M.D., of Boston; J. T. Eskridge, M.D., of Philadelphia.

In the absence of Dr. Seguin, Dr. Amidon was elected Secretary *pro tem.*

The report of the Secretary and Treasurer was read and accepted.

NOMINATIONS FOR MEMBERSHIP.

The following were nominated for membership: R. L. Parsons, M.D., of New York; and Charles F. Folsom, M.D., of Boston.

The following were then elected

OFFICERS FOR THE ENSUING YEAR:

President.—Dr. Isaac Ott, of Easton, Pa.

Vice-President.—Dr. W. R. Birdsall, of New York.

Secretary and Treasurer.—Dr. R. W. Amidon, of New York.

Councillors.—Drs. V. P. Gibney, and W. J. Morton, of New York.

The Secretary was directed to acknowledge with thanks the receipt of a letter and important papers from Dr. W. Becherew, of St. Petersburg.

The President was directed to appoint a committee to draft and present on behalf of the Association a letter of respect to the memory of the late Dr. Beard.

DR. MORTON, of New York, presented

A CONTRIBUTION TO TRAUMATIC NEURITIS, ILLUSTRATED BY A CASE FOLLOWING DISLOCATION OF THE HUMERUS.

The patient, who came into Dr. Morton's hands in February, 1882, after discharge from the hospital, was presented to the Association by Dr. Morton, and was examined with great interest. The case presented the following features of interest:

1. Danger of injury to the great nerve trunks by dislocation or reduction of dislocation.
2. An instance of ascending neuritis.
3. Presenting in association with neuritis, the rare symptoms of fibrous hyperplasia and neuro-muscular hyper-excitability.

The condition of the patient at date of first examination was as follows: Hand much enlarged, stiff, brawny, and club-like; arm wasted; skin glazed and waxen-like and flaccid; color, mottled purplish-red; arm flabby on palpation, resembling tissues subject to persistent chronic inflammation. Hand continuously cold; joints painful; nails curved, club-shaped, and exhibiting very rapid growth; absence of hairs on the hand.

Dr. Morton gave a detailed statement of the motor and sensory symptoms before and during treatment, and the electrical reactions in both arms to the faradic and galvanic currents; and traced with great minuteness the transfer of motor and sensory changes to the opposite member.

The treatment was by electricity, and severe blistering over the track of the brachial plexus, hot and cold douches, and cod-liver oil. Improvement under treatment had been marked.

The paper cites cases by surgical authors in comparison, and concludes that it is probable that efforts at reduction in difficult cases of dislocation of the head of the humerus into the axilla and the like, have more frequently produced the nerve lesion than the original accident.

Another interesting feature noted in the paper was that the left arm had become affected by an injury originally inflicted upon the axillary plexus, thus demonstrating the ascending nature of the neuritis.

The value of electrical examinations for diagnosis was here clearly shown; since without these examinations the evidence of transfer of trouble to the cord and opposite spinal nerves would have been impossible until much later.

In regard to the fibrous hyperplasia, the reader pointed out that while atrophy of the connective tissue in conjunction with other tissues was common, hypertrophy on the other hand was very rare. In the present instance, the hypertrophies resembled a number of small fibrous tumors situated on the palmar aspects of the phalanges. He had found but one similar case on record, and that by Weir Mitchell.

The condition of neuro-muscular hyper-excitability was tested by various members of the Association. Simple mechanical excitability is sometimes observed following spinal lesions; but in this case the phenomenon is more complicated since, when the muscle is once stimulated so that it contracts, the contraction remains relatively permanent and constitutes therefore a veritable *contracture*. This fact of contracture excited by irritation of motor points now existed in the left as well as in the right (originally injured) side. Would we find an exact parallel to the condition here observed, we must turn to Charcot's description of the condition discovered by him to exist during the lethargic stage of hypnotism and designated by him neuro-muscular hyper-excitability, a term adopted by the writer to indicate the similar phenomenon now, as far as he knew, observed for the first time in traumatism of peripheral nerves. The contracture present was due, not as commonly supposed to the degeneration of the muscle itself, but to the exalted activity of the spinal centre and a consequent reflex. Based on this theory, the pathogeny of the case was clear, viz., an ascending neuritis, a modification of the activity of the spinal nervous centre, and *hence*, neuro-muscular hyper-excitability in both arms.

The appearance of hand and arm at the beginning and during early treatment, was well exhibited by several photographs taken by the author.

Dr. Morton observed in conclusion that it is apparently clearly demonstrated by this case, that the condition of neuro-muscular hyper-excitability is not alone found in the hypnotism of the hysterical, but may exist in ascending neuritis which has reached the spinal centres.

DR. PUTNAM, of Boston, said that the etiology of this case was one that he had observed several times, and certainly was of considerable practical importance, but that even without dislocation, the condition of Dr. Morton's patient might be brought about. He had known two or three cases where the arm was either severely wrenched or thrown into a condition of strong and sudden extension, where the brachial plexus seemed pretty thoroughly disorganized. He had been in the habit of supposing that nerves stood a sudden strain very much less well than a prolonged strain, and that the very moderate degree of stretching which the nerves of the brachial plexus get in hyperextension of the arm, or the strain which some of the nerves of the sacral plexus are subjected to in sudden bending of the body or sudden replacing after bending, may cause them to suffer very severely.

As to the question of neuro-muscular hyper-excitability in the case of this patient, Dr. Putnam thought it opened up one of the very best fields for discussion. In this an examination of the patient undoubtedly obtained very exalted reflex responses, which are practically analogous with the neuro-muscular hyper-excitability of Charcot. The case had been given by Dr. Morton without doubt the only explanation that would cover it.

DR. V. P. GIBNEY, of New York, asked if the hyper-excitability was accounted for in this case in the same way as in compression myelitis, or was it explained by the excitability in the nervous centres in the spinal cord, or both.

DR. CHAS. K. MILLS, of Phila., thought that both explanations might apply. There exists an exalted reflex action where there is an irritated or an excited condition of the gray spinal reflex centres of the cord, and on the other hand the same condition exists where the cerebral inhibitory apparatus is cut off. From the nature of the case both causes are at work.

DR. WILLIAM A. HAMMOND said as to the treatment, that he thought one of the prime elements in the method of effecting cure of neuritis is to insure, as far as possible, absolute quietness to the nerve. In other tissues rest is one of the most essential elements in the cure. To an inflamed retina, for instance, much light is prejudicial. It had been his opinion for several years that the natural stimulus of the nerve is one of the excitants of the inflammation, and tends to keep it up, and that the transmission of it tends to aggravate the inflammation and retard the cure. It was on this account that he had for many years insisted upon absolute rest in the treatment of these cases, and in several instances employed stretching of the nerve.

DR. PUTNAM favored the use of ice continuously, day and night, for several days together, or at any rate for a great many hours together, as of the greatest possible advantage, care being taken to interpose several thicknesses of flannel, to prevent the cold causing irritation.

Dr. C. L. DANA, of New York, read some

NOTES ON THE USE OF HYDROBROMIC ACID IN NERVOUS AFFECTIONS.

Dr. Dana recited the first employment of hydrobromic acid, in 1875, by Dr. Wade, and since then by other physicians, and the experiments of Dr. Reichert upon the lower animals. It was found to depress the reflex functions of the spinal cord; but its effects upon the brain were not observed. Descriptions of the drug are not to be found in most of the therapeutical textbooks, and one author, as late as 1882, states that its real value has not been determined.

It has been used by the profession chiefly with quinine, with a view to lessen cinchonism.

Dr. Dana was led to experiment with this drug in the hope that it would have the beneficial effects of the alkaline bromides in epilepsy, without causing depression and scurvy.

Pure hydrobromic acid contains in 100 parts by weight 99 parts of bromine. One drachm of the pure acid is equal in bromine amount to about 90 grs. bromide of potassium, 75 grs. bromide of sodium, 66 grs. bromide of lithium, 73 grains bromide of calcium, 71 grs. bromide of ammonium. This drug therefore contains more bromine proportionately than any other of the bromine compounds, and is united with an innocuous metal. The average dose of the pure acid, assuming the medicinal and chemical equivalents to be the same, would be 10 to 20 drops.

Dr. Dana has used this drug in a very large number of cases, chiefly epilepsy, alcoholism, congestive headache, malarial headache, spermatorrhœa, vertigo, general nerve-weakness, various forms of neurasthenia, chorea, insomnia, hysteria, post-hemiplegic cerebral (vascular) disturbances, melancholia, etc.

Several cases of epilepsy in which the drug was used are set forth, among them an epileptic youth of 20, who had previously had various treatment since his ninth year; he was having attacks daily, and sometimes several in the day. Under the hydrobromic acid he often went one, two, and three weeks without any fit. The acid was given for six or seven months, in doses of ʒiv to ʒv daily. After a time it began to lose its hold. In three other cases, of milder type, the use of the drug stopped the fits as long as the patients were under Dr. Dana's care. In two other very obstinate cases, suffering both from *grand* and *petit mal*, there was no great benefit; one of the two latter, when put upon very large doses of bromide of soda, did better than upon the acid.

Dr. Dana concludes that, in epilepsy, hydrobromic acid cannot be used as a substitute for the bromides, except in the more controllable cases; yet that it undoubtedly has a controlling influence over the disease; and he does not feel certain that, if given in equivalently large doses, it might not be as efficient as the alkaline salts.

Hydrobromic acid is a good solvent for quinine, but does not prevent cinchonism, according to Dr. Dana's experience.

The best results from the use of the acid were in conditions of nervous irritability, congestive headaches, post-hemiplegic circulatory disturbances, irritable heart, and where a general nervous and vascular sedative is indicated.

Satisfactory sedative results are obtained from two-drachm, or even one-drachm, doses of the officinal dilute solution (ten per cent.). It is agreeable, non-irritating, and will cause no eruption or other symptoms of bromism.

DR. HAMMOND said he could not conceive that hydrobromic acid has any advantage over any one of the haloid or alkaline salts, or that it could act as a substitute. Its influence was much less efficient for the prevention of cinchonism than a small dose of bromide of sodium, combined with a dose of sulphate of quinine, although he was satisfied it had the effect of preventing cinchonism.

DR. J. J. PUTNAM, of Boston, read a paper upon

LEAD-POISONING SIMULATING OTHER FORMS OF DISEASE, AND ON THE DANGER OF MISTAKING BISMUTH FOR LEAD IN THE ANALYSIS OF THE URINE.

He stated that it was not his purpose to attempt an exhaustive description of the various obscure symptoms to which lead-poisoning may give rise.

They are certainly very numerous, and we are probably as yet quite ignorant as to how varied they may be in character. The main point was to urge careful routine examination of the urine in obscure cases. The instances which had come to his own notice, though not many in number, yet formed a considerable proportion of the cases, not clinically characteristic of lead-poisoning, in which he had had the urine examined.

The *first* case had presented a history of extreme anæmia with gradual failure of all the vital functions, and slowly progressive paraplegia.

The patient was a woman, 55 years of age. The whole course was about two years. The first symptoms were "numbness" and pricking of all four extremities, anæmia, and debility. This was followed by very slowly progressive paraplegia of the lower extremities, without localizing symptoms, and apparently of anæmic origin, with which she eventually died. A considerable quantity of lead was found in the urine, and no other cause could be discovered for the symptoms.

The *second* case was one of diffused interstitial myelitis of moderate intensity, with eventual improvement. The diagnosis was rendered somewhat doubtful by the fact that the patient had taken a small quantity of bismuth four weeks previously.

The *third* case (which had occurred in the hospital practice of Dr. F. Minot, of Boston) was one resembling the transient form of poliomyelitis anterior. Under the use of iodide of potassium the patient had greatly improved at the end of six weeks.

The *fourth* case was one with vague cerebral symptoms such as are seen in some forms of dyspepsia, lithæmia, and chronic nephritis. There was much improvement under the use of iodide of potassium.

In none of these cases were any of the distinctive marks of lead poisoning present.

Two other less obscure cases were reported, and two cases previously published by Dr. F. Minot and Dr. S. G. Webber were referred to, in both of which symptoms of latent sclerosis had been present.

Dr. Putnam then spoke of the important fact, first called to his notice by Prof. E. S. Wood, under whom the chemical work of the investigation had been done, that bismuth in the urine would be readily mistaken for lead, and said that he had undertaken experiments on this point.

He had himself taken from thirty to forty-five grains of bismuth daily for two weeks (the urine having been previously tested and found free from lead or bismuth), and had found that traces of bismuth were still to be detected in the urine, by the usual lead tests, as late as four weeks afterwards.

In testing for lead this possible cause of error should be borne in mind; and also the facts that before the examination for either lead or bismuth iodide of potassium should always be given for two or three days, and a large quantity of urine collected.

Discussion upon Dr. Putnam's paper was postponed, the hour being late.

Dr. Putnam exhibited *A Urinal*, to be used by females who are obliged to keep to a chair and are unable to leave the chair without difficulty.

EVENING SESSION.

DR. J. T. ESKRIDGE, of Philadelphia, gave a detailed account of the history of a man suffering from

GENERAL NEURALGIA.

The case was peculiarly interesting on account of the great difficulty in diagnosis.

The patient, about thirty years old, presented a nervous, irritable appearance. His father had died of some supposed inflammatory spinal trouble; mother still living, but suffering from pain in the abdomen. He had never contracted any venereal disease, and his three children seemed to be well developed and healthy.

In April, 1881, after sleeping in a damp bed one night, he was attacked with severe pain in the lumbar region of his spine. The spinal trouble lasted two months, but during the second month it was complicated by a painful condition of the left sciatic nerve. The pain in the leg could be relieved by firm pressure over the great sciatic nerve as it emerges from the pelvis. Throughout the attack he has been able to continue his work as moulder in an iron foundry, although it was done at the expense of great pain in the spine and affected nerve. In the following October, after having been confined in a hospital several weeks from a traumatic affection of the left ankle, he was again seized for one month by a return of the pain in the cord, and in all of the nerves of the left leg. During the next ten months he suffered more or less, but was able to work. In October, 1882, he remained five weeks in a hospital, suffering from another attack of pain, the lumbar region of the spine and the nerves of the left leg only being affected.

Jan. 15, 1883, he first came under Dr. Eskridge's care in the medical wards of St. Mary's Hospital. At that time he was scarcely able to walk, complained of great pain in the back and left leg, sleep was broken, appetite capricious, and bowels constipated; temperature 100°, pule 92, respiration 24. The spine was very tender on pressure in the dorsal and lumbar regions. All the superficial nerves of the left leg, thigh, and gluteal region were the seats of neuralgic pain. The nerves of the affected region were sensitive to light pressure.

The treatment consisted of rest in bed, blisters, and other counter-irritants over the affected nerves and lower portion of the spinal cord, counter-extension and extension of the left leg by means of pulley and weights, deep injections of morphia and atropia; and internally of ergot, bromides, strychnia, and many other agents used in neuralgia and rheumatism. Chloroform injections increased his suffering. Anti-syphilitic treatment was faithfully employed, but this gave no relief. Nerve stretching was resorted to in March, but only to increase his suffering.

In April, about one month after all active treatment had been abandoned, he began to improve under a mild faradic current.

April 11.—Electro-muscular contractility was well preserved, and about equal on both sides of the body. Electro-sensibility was increased in the left leg and in both arms. Tactile sensibility was decreased and surface temperature lessened over the entire neuralgic areas.

May 22.—Tactile sensibility and surface temperature were nearly equal on both sides of the body.

June 4.—It was noted that electro-sensibility was greater in the right leg than in the left. In the right leg, the faradic current, passing through the electric brush, was felt with a half inch of secondary coil, and in the left it was not observed until one inch of the secondary coil was used. Good faradic contractility was found in the muscles of both legs. On using the galvanic current, no reactions of degeneration were detected. The patellar, cremaster, and iritic reflexes, when investigated, were always found to be normal.

At present, the patient is steadily improving: he has gained in flesh and strength, and is able to do light work and walk comparatively long distances without suffering much pain, except in the coccyx and left popliteal space. The spine is entirely painless, both to pressure and the passage of a comparatively strong faradic current, nothing being done in the way of treatment, besides occasional applications, electricity alternating between the faradic and galvanic currents. During the last week, pustular eruptions have taken place over the superficial nerves of both arms and portions of the chest.

In conclusion, Dr. Eskridge considered the subject of diagnosis, and said: The trouble having commenced in the lumbar region of the cord, after the man had slept, one night, in a damp bed; its spreading to the sciatic nerve; the extension of pain up and involving the greater portion of the spinal cord and all the nerves of the brachial plexus, when taken in connection with the patient's deplorable condition at one time, and with the fact that the part first attacked, the lumbar portion of the cord, was, until a few weeks ago, the seat of great and constant pain, and very sensitive to pressure and the passage of mild faradic current, suggest the inquiry—Has not the case been one of general neuritis following inflammatory trouble of the cord or its membranes, and improved? In favor of general neuralgia he stated:

1. That we have a disease that has extended over a period of more than two years, made up of attacks of pain lasting from two to six months, in a man whose condition and general appearance to-day seem to be as good as they were after the first attack in the year 1881.

2. That several times, by firm pressure over the great sciatic nerve as it emerges from the pelvis, he had succeeded in relieving pain in the left foot and leg.

3. That in inflammatory conditions of the cord of so long duration, reactions of degeneration and other atrophic disorders would probably be found, and improvement, if it should occur, would be slower and less complete than it had been in the case which he had described.

4. That the left leg and right fifth cranial nerve were severely affected, while the left side of the face entirely, and the right leg almost entirely, escaped.

5. That pain was often shooting or stabbing in character, differing from the dull ache of neuritis.

He asked: Could not the case have had a syphilitic origin, and the inflammatory exudation have disappeared, leaving the man in his present condition?

Against this view he thought certain facts militated. When the patient first came under his care he was promptly put upon anti-syphilitic treatment, and notwithstanding the treatment was continued for a number of weeks, he grew worse, instead of better. The patient did not begin to improve until after that plan of treatment had been abandoned more than a month. Further, no anæsthetic zones or areas, such as had been pointed out as occurring in cases of syphilitic neuritis, were observed at any time.

DR. CHARLES K. MILLS, of Philadelphia, then read a paper on

LOCOMOTOR ATAXIA TERMINATING AS GENERAL PARALYSIS OF THE INSANE.

He said that the relation between locomotor ataxia and general paralysis of the insane had been a problem

of interest to neurologists and alienists since the investigations of Westphal, in 1863.

He related the following case: P., æt. 47, at the time of coming under observation, was a man of good constitution, noted for his strength and endurance, but for three years he had not been well, during most of which period he had been treated by different physicians for rheumatism. He was addicted to venereal excesses, and used and occasionally abused alcohol. Many years before he had had a chancre, but had not subsequently had any of the ordinary evidences of secondary or tertiary syphilis. He had first suffered from darting or shooting pains in his feet and legs, soon he experienced sensations of numbness and tingling in his feet, and later in the little and ring fingers of the left hand. For a short time he was troubled with double vision, and his sight had diminished a little in acuteness.

The results of an examination made during the first week he was under observation, were as follows: No paralysis was made out; galvanic and faradic irritability were well preserved. He could not walk well after dark. He swayed and tottered on trying to stand with his heels together or with his eyes shut; and he could barely manage to stagger a few steps with his eyes closed. Paroxysms of sharp, sudden pains in the limbs were more frequent. He was awkward with his hands in dressing.

A peculiar sense of constriction on drawing in the lower part of the abdomen, had annoyed him for several months. Sexual desire had diminished. He had no delusions, and was fully able to attend to his business, which required a large amount of physical and mental exertion.

Under the use of nitrate of silver, galvanization of the spine, and faradization of the extremities, continued for several months, he improved remarkably; but after remaining better for a few months he again relapsed, and now he got steadily worse. Occasionally, however, he would temporarily improve. The anæsthesia of his feet and hands deepened; the straggling gait returned and grew worse; every two or three weeks he would have frightful attacks of lancinating pains.

Decided mental symptoms first began to make their appearance two years after first coming under treatment. He spent his money very freely upon others as well as upon himself. His ideas became queer and lofty; but the delirium of grandeur did not develop thoroughly until nearly a year later, when he began to talk and act in the most preposterous manner. About the same time, a peculiar stagger in his speech, a slight twisting of the mouth to one side, and some tremor of the tongue and lips, became noticeable when he talked.

Nearly three years after the notes first made, and almost six years after the development of ataxia pains, he was sent to the Insane Department of the Pennsylvania Hospital where Dr. Mills occasionally visited him. His delusions became of the wildest character; and he became irritable and hard to manage. Anæsthesia, tremor of tongue, etc., increased. On two occasions he had slight apoplectiform attacks, once accompanied by a slight spasm.

Later he was removed to the State Hospital for the Insane, at Danville, Pennsylvania, where he remained until his death, which occurred five years and four months after first coming under the care of Dr. Mills, and about eight years after he was first affected with ataxia pains.

A post-mortem examination of the brain and spinal cord was made. The pia-mater over both cerebral hemispheres, particularly in the postero-frontal and parieto-temporal regions, was opaque, congested and adherent at points; decortication being marked, convolutions were atrophied. The pia-mater of the cerebellum, especially over the superior vermiform process, was deeply congested and adherent. The pia-mater of the spinal cord was thickened; and the cord presented an irregularly shrunken appearance. Microscopical examination showed marked sclerosis of the posterior columns of the spinal cord throughout its whole extent, and that inflammation and thickening of the pia-mater were also present everywhere. The sclerosis was most pronounced in the lumbar region, decreasing in intensity as the cord was ascended; but it was well-marked throughout, both in the columns of Gall and in the posterior root zones. The medulla oblongata on one side was much sclerosed, and slightly so on the other side. Sclerosis was also present in the pons, crura, optic thalami, and convolutions examined, and in the cerebellum.

The pathological appearances shown by the microscope corresponded closely to those mentioned by Westphal. The posterior as occurring in the spinal cord in dementia paralytica. According to him, the posterior columns show few or no sections of nerve fibres, and their place is taken by a connective-tissue substance. In the cervical region Gall's cuneiform columns are especially affected; in the dorsal and lumbar regions, however, the entire area of the posterior columns is involved. In fresh preparations numerous granular fat-cells and corpora amylacea are found.

In this case the spinal symptoms were the first to appear. Three years before coming under the care of Dr. Mills, he began to suffer with the lancinating pains of posterior sclerosis. Although, when first seen by him, and until he improved under treatment, he suffered at times from mental anxiety and sleeplessness, apparently the result of the pain and other distressing symptoms of the ataxia; no typical mental symptoms appeared until more than two years after coming under Dr. Mills' care, and more than five years after the appearance of the first symptoms of spinal trouble.

Dr. Mills referred to the views of various authorities with reference to the relation of locomotor ataxia and general paralysis of insane. According to Westphal, with whom Hammond agrees, no direct relation exists between the morbid process in the cord in posterior spinal sclerosis, and that in the brain in general paralysis of the insane. According to these authorities, neither disease is secondary to the other. They simply coexist as the expression of an excessive proclivity to disease of the nervous system, just as any other two diseases may be present, one in the brain and the other in the cord, without there being any direct interdependence between them. Locomotor ataxia is by no means uncommon in patients affected with the other forms of insanity. Hamilton (*Medical Record*, July 29, 1876) discusses the relation of these two affections. Leidesdorf has related one case in which general paralysis was preceded by spinal symptoms. Maudsley speaks of other cases. Calmiel says that in many cases the changes proceed from the cord upwards, and Baillarger endorses his views. Charcot has proved very conclusively that disseminated sclerosis can exhibit all the symptoms of general paralysis of the insane. Cases reported by Obersteiner, Hamilton, Plaxson, Mickle, and others were also referred to by Dr. Mills. He dwelt in conclusion upon the importance of the occurrence of thickening of the pia mater and other evidences of a condition of chronic inflammation of this membrane.

DR. G. M. HAMMOND inquired if there were any patellar tendon reflex symptoms, and Dr. Mills answered there was diminution.

DR. SHAW said he had seen one case of locomotor ataxia followed by general paralysis, but there was no

extravagance, it being of a dementia type. The patient died in epileptic convulsions.

DR. BIRDSALL, of New York, had examined post-mortem the case mentioned by Dr. Shaw, and referred to one or two interesting points in the condition of the cord. It presented, throughout its length upward from the lowest part of the lumbar enlargement, the appearance of an ordinary sclerosis of the posterior columns, in which the columns of Gall were more prominently shown in the upper portions, and the columns of Burdach and Gall in the lower portions. In addition to this there was, particularly in the posterior half of the transverse section of the cord, a peripheral sclerosis, or cortical sclerosis as it might be termed, which Dr. Birdsall thought was secondary to a slight meningitis, and, as he imagined, was a condition which existed in the case described in Dr. Mills' paper.

DR. MILLS, in reply to an inquiry, replied that aside from a sclerosis extending to a slight depth into the cord, meningitis did exist in the case described by him, and he considered it a very important point in connection with that and similar cases.

DR. WEBBER, of Boston, mentioned two or three cases; one, that of a prominent merchant, going to show the characteristic lancinating pains. These pains began in his forty-fifth year, and lasted five years; and then a second five years also associated with complete paralysis of the bladder, accompanied with most exquisite suffering. From the tenth year of the locomotor ataxia, Dr. Webber became acquainted with the patient and noticed then complete absence of the tendon reflex and cremaster, and the posterior sclerosis advanced in spite of all that could be done. In this case syphilis could be excluded. The patient finally showed all the symptoms of *dementia paralytica*, and died completely demented.

THE DISCUSSION OF DR. PUTNAM'S PAPER,

read at the afternoon session, was then taken up.

DR. WEBBER said that we have not got to the bottom of the influences which lead may have upon the nervous system. In connection with the various pricking and numb sensations and the parasthesia, etc., mentioned by Dr. Putnam, he said he had noticed, in nearly all cases of lead paralysis or lead poisoning affecting the spinal cord, coming under his observation, that the patients had various disturbances of sensation, but sometimes so slight and apparently insignificant, that patients paid very little attention to them, and had to be cross-examined in regard to them, and sometimes return to the subject repeatedly in order to ascertain whether these disturbances did not actually exist. Dr. Putnam had pointed out in his paper, one source of error in tests of the urine for lead, and Dr. Webber adduced another, viz., if the water is allowed to stand and decompose, becoming partially alkaline, a chemical reaction takes place between the alkaline liquid and the glass, and lead is precipitated from the glass.

DR. MILLS thought a sufficiently comprehensive view was not taken of the nature of cases of this kind. Every one in this branch of medicine had seen cases of metallic poisoning result in paralysis, and also diphtheritic affections. Just as had been pointed out by Dr. Putnam, while we are likely to have a typical form of the disease, we are likely to get affections of all sorts, cerebral, spinal, and so on. He had seen not only bilateral paralysis of the extensors in lead paralysis, but also some forms of tremor. He had seen within two days a well-marked case of lead poisoning, with weakness of all the limbs and tremor. It had been suggested that these poisons were protoplasmic poisons, and he thought there was a great deal in it.

DR. PUTNAM closed the discussion by insisting upon systematic examination of the urine in these cases to see whether lead could be found, even when there is no reason to suspect it from the general symptoms. He also urged the importance of carefully excluding the possibility of indications of lead from the presence in the system of bismuth, which should not have been taken for a considerable time.

THURSDAY, JUNE 21ST, SECOND DAY.

AFTERNOON SESSION.

DR. W. J. MORTON, *Vice-President*, in the Chair.

Upon the favorable report of the Council, Dr. R. L. Parsons, of Sing Sing, was unanimously elected by ballot to membership.

THE PRESIDENT, DR. ROBERT T. EDES, of Boston, then presented a paper on

THE EXCRETION OF PHOSPHITES AND PHOSPHORUS AS CONNECTED WITH MENTAL LABOR.

The paper consisted in a brief record of some experiments made upon himself to test the alleged increase in the excretion of phosphoric acid after mental labor. They were made chiefly in the afternoon as being the time during which it was easiest to secure tolerable uniformity in the other conditions.

In one set the time was partly occupied by a lecture or some similar exercise, and in the other passed as nearly in a state of mental vacuity as possible. Some of the later experiments, however, embraced a larger number of hours, employed mostly in reading or writing, and also the succeeding night.

The results showed no material difference in the average of phosphoric acid excreted, although the range of variation in individual experiments was considerable.

The average of the work hours was grm. 0.1153 of phosphoric acid per hour, and of the leisure hours grm. 0.1157. The quantity seemed to be more affected by the amount of urinary water than by any other circumstance, but did not follow this exactly. On several occasions the amount of water was considerably diminished during a lecture, and it is possible that this may be due to a temporary congestion of the brain, and consequent anæmia of the kidneys. It might be concluded from these experiments (so far as their limited number would justify any conclusion) that the demonstration of the value of phosphorus as a mental stimulus or tonic must rest rather on a clinical than a chemical basis.

DR. PUTNAM asked how the results corresponded with those found by others in similar investigations.

DR. EDES replied that he had not been able to find any others, except the vague statement made by Dr. Holmes in one or two of his essays, that if a clergyman did his duty on Sunday you could find it out by the amount of phosphorus in his urine on Monday. Dr. Holmes said he could not tell where he got the authority for the statement, but knew he had authority for it; therefore Dr. Edes' conclusion was that there was nothing distinctive about the finding of the phosphorus in urine, so far as he could find.

DR. JEWELL said that while he had not made investigations upon the subject such as those of Dr. Edes, yet looking at the matter in the light of common-sense, he had never been able to see why an organ, small comparatively as the brain should, even in a tolerably protracted mental effort, so extraordinarily increase the excretion of the quantity of phosphates as to make any very great change in the amount found in the urine. It seemed to him a thing entirely unreasonable. He had never found any reason for thinking that any such quantity was thrown off in the waste matters from the brain as to make much difference in the composition of the urine. It would be a surprising thing if

there was any increase in the production of phosphorus in the urine from brain activity, and the thing seemed almost absurd.

DR. WEBBER, of Boston, read a detailed history of several *Cases of Locomotor Ataxia*, which were of especial interest on account of unusual symptoms and also of the marked remissions in their course. As it consisted of a large mass of details, all of which are essential to its interest and value, a suitable abstract of Dr. Webber's paper cannot be presented here.

DR. AMIDON, of New York, presented a case of *Tetanoid Pseudo-Paraplegia* occurring in a child, the tetanoid symptoms being preceded by a train of symptoms indicating subacute hydrocephalus. He made the query whether the cerebral trouble could not, by causing descending changes in the cord, account for the tetanoid symptoms, the etiology in most cases being very obscure

DR. AMIDON also presented two *Anomalous Cases of Parkinson's Disease*, the peculiarity consisting of an entire absence of tremor, every other symptom of paralysis agitans being present.

DR. GIBNEY, of New York, brought before the Association for examination two very interesting *Cases of Progressive Muscular Atrophy*.

DR. W. J. MORTON read a paper on the

TREATMENT OF SCRIVENER'S PALSY,

and exhibited a device in the form of a thimble of metal to cover the entire index-finger, having a longitudinal opening throughout its length, so as to be adjustable to the size of the finger, and having a slide at the tip for holding a stub-pen. The theory of the apparatus is that by enforcing extension and preventing flexion, the apparatus would not only enable the person to write with the affected hand, but by removing the cause of irritation lead to restoration.

FRIDAY, JUNE 22D, THIRD DAY.

AFTERNOON SESSION.

Dr. J. Leonard Corning was nominated for membership, and the nomination was referred to the Council.

The Secretary presented to the Society on behalf of the author the finely illustrated work of Dr. Mason, of Boston, on the *Central Nervous System of Reptiles*.

DR. G. M. HAMMOND presented a patient to the Association, stating that there was no doubt that it was a real

CASE OF LOCOMOTOR ATAXIA WITH RETURN OF THE REFLEX,

which was very apparent in one leg; all his ataxic symptoms had disappeared, except paralysis of the sphincter, he being still unable to wholly hold his water.

To various inquiries Dr. Hammond answered that the treatment in the main had been iodide of potash, and the electric wire broom to the spine; that neither was relied upon mainly, but as taken together. The preparation of iodide of potash was the saturated solution, twenty-five grains three times a day. At first the patient could not see well, he could see partially; at the distance of ten feet he could not see the hands of a large clock; he could not write; there had been slight arm symptoms.

DR. MILES, of Baltimore, read a paper on "*Nutritive Alterations in the Hand, from Pressure of the Head of a Dislocated Humerus in the Axilla*," accompanied by photographs.

DR. BURT G. WILDER of Ithaca, read a paper on

THE BRAIN OF A CAT LACKING THE CALLOSUM.

Although there have been recorded several cases of more or less nearly complete absence of the great cerebral commissure in human beings, the specimen exhibited (with photographs) seems to be the only case of the kind among the lower mammalia, being the only case occurring in the Anatomical Laboratory of the Cornell University among the several hundred cats' brains there examined. There is not a trace of the callosum, nor of the fornix beyond the dorsal limits of the portæ (foramina Monroi); the præcommissure and medicommissure are larger than usual. Unfortunately nothing whatever is known of the history or habits of the cat. Now that the unique specimen has been submitted to the Association, Prof. Wilder will feel more free to dissect it.

DR. WILDER also read a paper on

THE ALLEGED HOMOLOGY OF THE CARNIVORAL FISSURA TRUCIATA WITH THE PRIMATIAL FISSURA CENTRALIS.

Referring to the assumption by T. Lauder Brunton (*Brain*, January, 1882) that these fissures "correspond," Prof. Wilder made the following suggestions: 1. Writers should specify whether by "correspondence" they mean *analogy* or *homology*, a relation based upon the position of a fissure, based its location among experimentally determined "motor areas," or a relation implying identity as determined by embryology and comparative anatomy. 2. The present disagreement of competent authorities respecting the homology of these two fissures should restrain both physiologists and zoölogists from assuming the correctness of any particular view; for example, the human centralis has been homologized with not only the cruciata but the superorbitalis, the coronalis, and the ansata together with the coronalis (in connection with which last idea was shown a fœtal human brain exhibiting the somewhat rare condition of an interruption of the centralis); the cruciata has been homologized with not only the centralis, but with the first frontal, the calloso-marginalis, and the occipito-parietal. 3. The surest method of determining the true homology seems to be the one which is outlined in Wilder and Gage's *Anatomical Technology*, to make careful and extended comparisons between the brains, especially fœtal specimens, of man, monkeys, and the *lemurs* on the one hand, with those of cats, dogs, and *seals* on the other. The lemurs are primates with some characters of the carnivora, while the seals, though carnivora, have the occipital lobe and the postcornu of the procœlia (cornu posterius of the ventriculus lateralis).

AFTERNOON SESSION.

DR. W. J. MORTON read a paper entitled

REMARKS ON THE TREATMENT OF MIGRAINE.

After commenting upon the confusion in which the entire subject of the treatment of migraine exists, and enumerating the different remedies empirically employed, Dr. Morton proceeded, upon the basis of familiar facts, to inquire whether the disjointed assaults upon the disease might not be arranged into a systematic method of treatment upon the vaso-motor theory of the disease, and referred to the hypothesis of DuBois Reymond, that the symptoms of migraine or hemicrania may be explained by the existence of a contraction or tetanus of the muscular walls of the bloodvessels of the affected side. Dr. Morton said: In the vaso-motor theory we find a definite working basis for the practical treatment of the disease, in which clinical observation and experimental physiology are singularly in unison. According to this hypothesis vascular dilatation or contraction of the arteries within the cranium, and a corresponding condition externally, plus certain characteristic oculo-pupillary phenomena, form collectively a group of symptoms similar to those produced by irritation or destruction of the ordinarily

accepted vaso-motor mechanism. But whence the origin of the stimulus that awakes the functions, or in other words, the symptoms, is beyond our present knowledge. Whether in the vaso-motor centre itself, or in the local centres of the arteries, contracted or dilated; in the ganglion or tract of the cervical sympathetic; or in some distant sentient surface (reflex action); or whether we have to deal with chemical stimuli (changed quality of blood) acting upon the central vaso-motor centre, we are entirely ignorant. The best evidence points to the cervical sympathetic, or its corresponding spinal centre, as the seat of the disease. And according as one or the other exists, we have the angeio-spastic or the angeio-paralytic type of the disease. The diagnosis of the type then, and not the simple diagnosis of the disease itself, determines the treatment; often by diametrically opposed measures or remedies.

Having mentioned the general grounds of diagnosis, Dr. Morton stated that out of thirty-five private cases, but six were of the paralytic type, and concludes that it will be generally admitted that the spastic type is by far the more common. The treatment of the angeio-spastic type is by bromide of sodium, 60 grs. at the very outset, repeated in an hour and a half if the attack does not cease. This he had seldom known to fail of bringing almost immediate relief, where otherwise the patient would go through the usual course of twenty-four to forty-eight hours of suffering. The patient should then be put upon a course of the same remedy, giving 15 grs. three times a day for from three to six months. Cod-liver oil alternating weekly with maltine, and also a preparation of iron, should be given in conjunction with the bromide of sodium treatment. Dr. Morton said: I know there is a widespread prejudice against the "bromide treatment," owing to its depressant action upon the economy, but I believe that this objection applies only to the potassium salt. In the bromide of sodium treatment, by careful management with tonics, the slight adynamic effects may be counteracted, while, at the same time, those very exalted functions of the tissues which we wish to restrain are held suspended. To the objection often made to the bromide of sodium treatment—viz., that the bromide of sodium reduces the amount of blood in the brain, and should not be used in the treatment of the spastic type where anæmia already exists—I answer that in this type, paradoxical as it may seem, the bromide actually increases the amount of blood in the brain over and above the previously existing ischæmia due to the spasm of the vessels. This it probably does by depressing the excitability of the irritated vasomotor mechanism.

Treatment of the spastic type of migraine by glonoin or by nitrite of amyl seems to have a secure foundation in clinical experience, the glonoin producing the more lasting effects of the two, and being in many instances of remarkable efficacy. Glonoin relieves the angeio-spastic form of the disease by its action upon the vaso-motor mechanism. It probably removes irritability of the centres. Both the bromide and the glonoin may be used in the same case, and often with better results than by either alone, the bromine being given before meals and the glonoin after meals.

The angeio-paralytic type. The diagnosis being once made, measures to restore the tonus of the relaxed arterial walls are called for, and may be theoretically called into activity by strychnia in increasing doses, until the full physiological effects are produced, and then returning to the original dose and repeating. But the chief remedy indicated in this type is ergot, its action being to produce vaso-motor spasm.

DR. HAMMOND said, in reference to the diagnosis of the two different kinds of migraine, that one important means is the difference in temperature in the two sides of the face. In the paralytic form, the temperature of the external auditory canal is from a degree to two degrees higher on the affected than the sound side; and in the spastic variety it is as much as that lower than on the sound side. This is a very simple means of determining what kind it is, when sometimes without that it is difficult to determine. Dr. Hammond said he had met with two cases where the patients had suffered from the paralytic variety on one side and the spastic on the other, and failed to cure either of the cases, and he inquired how such a case should be treated. Again, he wondered why Dr. Morton had not laid more stress upon the administration of strychnia in the paralytic variety, which he thought more efficacious than ergot, strychnia in gradually increasing quantities being very valuable.

DR. MILLS said that he had found that it may be possible to have the two varieties, both paralytic and spastic on the same side.

DR. DANA thought it rather strange that a cut-and-dried treatment, based upon the paralytic or spastic condition should be so prominently put forward. In his experience he had not been able to distinguish between the two forms in many cases. As to treatment, he had found the fluid extract of cannabis indica especially effective when the attack was coming on, given in small doses, frequently repeated.

DR. BIRDSALL exhibited statistics collected from various sources, including his own, tending to show *the relation of syphilis to locomotor ataxia.*

DR. BIRDSALL also exhibited *a hand electrode* of his own device for getting electrical reactions, and also for therapeutical purposes.

EVENING SESSION.

DR. DANA, of New York, read a

NOTE ON THE TREATMENT OF CHOREA BY THE SEDATIVE GALVANIZATION OF THE BRAIN.

He described the objective and subjective phenomena resulting from galvanization of the brain, referring to the experiments of Loewenfeld and of Legros demonstrating the vascular change produced by this procedure. A review of the work of various experimenters was given. He deemed the therapeutical and physiological effects due in part only to the action upon the vessels, and in part to the change of tissue and irritability and tissue metamorphosis. He advocated the abandonment of the term current direction, and the adoption of the polar nomenclature and method. Nodal galvanization of the brain increased the tone of the bloodvessels, caused diminution of tissue irritability, and was therefore indicated in chronic functional irritative diseases like chorea. He had used nodal galvanization of the brain in eight cases of chorea minor, with a favorable result in each case. One case of long standing had been promptly checked in two weeks. A very violent and obstinate case which had resisted arsenic, rapidly improved under electricity. The average duration of the disease was less than forty days. Galvanization of the brain should be pursued daily for from seven to ten days. The positive pole with a large sponge electrode was placed over the motor centres, the negative pole in the opposite hand. A current of three to six Stöhrer's cells was used. Arsenic might be given at the same time, especially if the galvanizations could only be given three or four times a week. Confirmatory results by Erb and Berger were referred to.

DR. BURT G. WILDER, of Ithaca, then read a paper on

THE REMOVAL AND PRESERVATION OF THE HUMAN BRAIN.

Assuming the great value of an accurate knowledge of

the gross structure of the human brain as a foundation for histological research and for comparative anatomy and psychology, Prof. Wilder urged that in all museums and in the private collections of medical men, and especially teachers, there should be preparations of brains removed without the risk of tearing delicate parts, and perfectly preserved. For the sake of obtaining such brains, no fine labor or expense should be spared, and the other parts of the head should be sacrificed if necessary. Prof. Wilder then proceeded to give an account of the methods of dissection, injection, and hardening now employed in the anatomical laboratory of Cornell University, the primary object of which was to make reliable microscopic preparations of the brain.

PROF. WILDER also read a paper on *Some Points in the Anatomy of the Human Brain.* A large number of preparations and photographs were shown illustrating the various points.

DR. SEGUIN, of New York, who is now in Europe, sent to the Society a paper entitled

NOTES ON SPANISH ASYLUMS FOR THE INSANE.

This paper consists of notes taken during the past winter while visiting the principal accessible Spanish asylums. An account of each institution was given; their statistics are quoted; their methods of treatment detailed, criticised, and suggestions for improvement advanced. According to the statistics collected, there was an apparent increase of insanity in Spain during three years of thirteen per cent. The Spanish alienists gave estimates of the frequency of general paralysis varying from two to twenty-five per cent. As causes of this form of insanity, they enumerate alcoholism, excessive intellection, and syphilis as among the most common.

It was found that, with the exception of half a dozen men, most of those in charge of the insane had but little knowledge of the subject of psychiatry. But few of them could read any language except French and Spanish, and they seemed to have the vaguest knowledge of the wonderful influence of non-restraint and occupation, as practised in the English and Scotch asylums. There is very little clinical instruction in mental diseases, and there is no association of alienists.

The general management of private asylums is very good. The Provincial are all bad; want of grounds, small size, want of rooms or materials for amusement or instruction are marked. There was often an apparent notion that many patients were "utterly demented," unconscious of comforts or discomforts, and indifferent to their surroundings; this idea leading to neglect and cruelty. With the exception of at the Valencia asylum, little and harmless restraint is used. At Valencia, not only were camisoles, ordinary muffs, wristlets, etc., employed, but there was in use an iron belt, made in two segments, connected behind by a hinge, and closing in front by a nut and screw. The belt is five centimetres wide and four millimetres thick, and has a manacle on each side for the wrists which gives the arms only about three inches play. This iron apparatus is not lined or padded in any way, and weighs nine or ten kilos.

In one long, narrow, dismal room there were between thirty and forty women squatting, nearly naked, on straw. Their only clothing was a coarse shift, open in all directions. Over this howling, moaning, singing, and rocking crowd a woman (assisted by a bad-looking man) held sway. The males were equally devoid of comforts and clothing, and this in a climate making winter underclothing and a fall overcoat comfortable to a New Yorker. They appeared to have no occupation, diversion, or amusement.

Whatever their faults as alienists, everywhere the visitor was met by the asylum physicians with the most extreme courtesy, and the most complete readiness to show everything, good and bad, to the guest.

NEW HAMPSHIRE MEDICAL SOCIETY.

Ninety-third Annual Meeting, held at Concord, January 19 and 20, 1883.

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, JUNE 19TH, FIRST DAY.

THE Society was called to order at 11 o'clock A.M., by the *President*, DR. A. H. CROSBY, of Concord, and prayer was offered by the Chaplain, Rev. F. D. Ayer, of Concord.

The meeting was large for a State where the profession are so widely separated; as it was found, that out of over two hundred active members, about one hundred and thirty were present.

DR. F. A. STILLINGS, *Chairman of the Committee of Arrangements*, explained to the members the programme for the day, and invited visiting delegates to the Anniversary Dinner.

The usual committees were announced by the Chair, and various routine business incident to the opening session was transacted.

The committee on the reception of delegates announced through the Chairman, that Vermont, Massachusetts, and Rhode Island were represented, and the delegates from those States were introduced to the Society.

THE REPORT OF THE COUNCIL,

which had met the evening previous, was read by the Secretary, and it appeared that twenty-five new members were recommended for election, and that only four deaths had occurred among the members during the past year.

An application for a district society had been granted. Various questions of Ethics had been disposed of, and the following preamble and resolutions relative to the

LIBRARY AND MUSEUM OF THE SURGEON-GENERAL'S OFFICE

were recommended for adoption by the Society.

Whereas, The medical profession of the United States, as well as of foreign countries, have contributed to the collections known as the Medical Library and Museum of the Surgeon-General's Office, at Washington, D. C., and

Whereas, These collections have become the most complete and valuable of their kind in the world; being of inestimable value to the profession, and of national importance to the public, and

Whereas, We firmly believe, that as citizens, the medical profession of this country have claims upon our government to protect and preserve these records of our self-sacrificing professional labor, and,

Whereas, By reason of the building in which these collections are now deposited, being reported by the War Department as insecure, and in constant danger of destruction by fire, from which would ensue irreparable loss; therefore,

Resolved, That in the opinion of the members of the Medical Society of New Hampshire, the great value of these collections demands from Congress such fair consideration of the merits involved as will secure an appropriation of sufficient amount to provide for the construction of a fire-proof building suitable in all its appointments to protect and preserve all books and material now on hand, or that will probably be contributed in the future.

Resolved, That the medical profession of New Hampshire, in common with that of all the other States of the Union, are a unit in their belief that a

library like that of the Surgeon-General's Office, will prove of much benefit to the profession and ultimately to the public, and that having a representation politically in the ranks of the great political parties of the country, this great work is entitled to consideration as much as any subject connected with internal improvements, or the construction of public buildings for the use of courts, customs, or postal facilities.

Resolved, That the President and Secretary of this Society, send a copy of these resolutions to each member of Congress from New Hampshire, also to the Surgeon-General, U. S. A.

The report of the Council was accepted.

At twelve o'clock the PRESIDENT read his

ANNUAL ADDRESS,

of which the following is a brief abstract.

He took for his subject the "Country Practitioner." He compared the country doctor of 50 years ago, who gathered his own herbs and made his own decoctions, with the present physician, who has the assistance of vast laboratories to aid him in his profession. The country doctor believed in the lancet, and in freely bleeding the patient in a variety of conditions. In the city circles this practice has gone into disuse, but bleeding is still occasionally resorted to. His charges have always been low, compared with rates prevailing in the city. In old times he carried on a farm as well as attended to his patients. His chief trouble was in getting established, because the selectmen were liable to warn him out of town if he was poor.

In old times the medicines were few and simple, the common remedies of to-day being almost unknown. One shilling was the fee for an office visit, the most important operation being performed for one dollar. His office was a terror to the uninitiated, but his visits were cheerful to the patient. The speaker gave a cursory glance at the history of medicine in the old world, leading over to the sources of information available to the student in pursuit of knowledge. In surgery the old country doctor was almost as helpless as in medicine.

He complimented the country surgeon on his happy faculty to improvise instruments and appliances to meet emergencies, and instanced many cases in which the carpenter's shop and the tinsmith had assisted the country practitioner to save life and limb.

The address was followed by an *Oration* by DR. GEO. W. HATCH, of Wilton.

DR. F. A. STILLINGS, of Concord, then read a paper on

THE TREATMENT OF INDOLENT ULCERS AND CARBUNCLE.

In carbuncle it was his practice to make a crucial incision as soon as called for, and with a hypodermic syringe introduce into each angle a few drops of carbolic acid of full strength, which at once produced an anæsthetic effect, allayed pain, and hastened the sloughing necessary to bring about resolution. The treatment recommended for indolent ulcers was painting the edges with a strong solution of nitrate of silver and applying a double roller bandage. The speaker also referred to the manner in which cloth or felt splints could be made at short notice from a solution of gum shellac.

DR. WM. T. SMITH, of Hanover, read an essay upon

COLDS.

He claimed that the subject, though a familiar one, is well worthy of the attention and study of medical men. A cold is essentially a disturbance of the nervous system caused by a lowering of the surface temperature of the body, and usually manifesting itself by a catarrh of the respiratory tract, though it may affect almost any organ or tissue. The writer described briefly the great historical epidemics of influenza, which are generally supposed to have been caused by a germ in the atmosphere, and raised the question whether the prevalent catarrhs of the past season might not rightly be called influenza, and whether, after making due allowance for exaggeration in the old writers, and the greater severity of many diseases in early periods, these famous epidemics might not themselves be brought into the category of colds due to unsanitary surroundings and atmospheric change. The best treatment for colds is prophylactic. Habits which invigorate the whole system, and especially the skin, which is the point of attack. Daily bathing and friction of the surface is more valuable than any other single measure. The speaker alluded to the nervous shock which some receive when exposed to the cold, and said that any remedial measure that would raise the standard of vital force, and offer more inherent resistance to such shock, would prove of great advantage.

The oration entitled *The Great Work*, by DR. BLAISDELL, of Controcook, was well received, and a paper on *Water Pollution*, by DR. WATSON, Secretary of the State Board of Health, was a *resumé* of the dangers so often met with in all sections of the country, with an abstract of the results of such investigations the Board had made, and closed with an offer to the members of assistance to investigate instances in which there was reason to believe water pollution was a factor in producing the disease, as a series of such investigations would prove of value when properly conducted and tabulated.

DR. D. S. ADAMS, of Manchester, continued a report commenced at the last annual meeting of a case of *Pulmonary Abscess*, and brought the patient before the members to illustrate his condition as compared with one year since. There is still an open pulmonary fistula, through which air will pass when forced inhalation is practised, yet he has gained several pounds in weight, and the report said he should have considerable hope that he might attain a comfortable degree of health for a few years if his habits did not lead him to all kinds of excess.

DR. P. A. STACKPOLE, of Dover, read a dissertation on *Venesection*, and took the ground that the fact that blood-letting had become one of the lost arts was not of an advantage to the profession or the public.

He claimed that in many diseases the course could be shortened or modified far better with the lancet than with drugs, yet the diagnosis must be correct, for it was far too potent an agent to use in cases in which mere guesswork was the foundation for treatment.

WEDNESDAY, JUNE 20TH, SECOND DAY.

The Society came to order at 8.30 A.M., and reports of district societies, delegates to other States, and delegates to Dartmouth Medical College were read, and considerable miscellaneous business was transacted, and the following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—John W. Parsons, M.D., of Portsmouth.
Vice-President.—John Wheeler, M.D., of Pittsfield.
Treasurer.—D. S. Adams, M.D., of Manchester.
Secretary.—G. P. Conn, M.D., of Concord.
Anniversary Chairman.—A. P. Richardson, M.D., of Walpole.
Executive Committee.—Drs. A. H. Crosby, Charles R. Walker, of Concord; and George D. Towne, of Manchester.

A Council consisting of twenty members, and a Board of Censors made of ten members, was chosen, representing the various sections of the State.

The Next Annual Meeting will be held in Concord on the third Tuesday of June, 1884.

RHODE ISLAND MEDICAL SOCIETY.

Seventy-second Annual Meeting, held at Providence, June 21, 1883.

(Specially reported for THE MEDICAL NEWS.)

THE Rhode Island Society held its Seventy-second Annual Meeting in Lyceum Hall, Providence, Thursday, June 21st. The *President*, DR. JOB KENYON, occupied the Chair.

The *Secretary*, DR. GEO. D. HERSEY, presented his report, showing that four meetings of the Society had been held during the past year; that the present active membership numbers one hundred and eighty-five, and that three Fellows have died since the last annual meeting, viz., Drs. George Capron, Geo. E. Mason, and Nathaniel A. Fisher, all of Providence.

The Report of the Treasurer, DR. C. H. LEONARD, was as follows:

Received, ...	$1,083 21
Expended, ...	723 19
On hand, ...	$360 02

It was voted to add the sum of $490 to the Publishing Fund.

The Reports of the Delegates to the American Medical Association were called for. Drs. D. Homer Batchelder and Ariel Ballou responded, speaking in favorable terms of the proceedings at the Cleveland meeting, and of the general outlook for the future of the Association.

The Board of Censors reported the names of five applicants for membership, said applications to lie over till the next regular meeting, according to the by-laws.

Dr. R. M. Griswold, of North Manchester, Connecticut, was introduced as a *delegate from the Connecticut Medical Society*.

Dr. H. R. Storer, of Newport, a *delegate from the Newport Medical Society*, being called on, spoke pleasantly in behalf of the Society he represented, whose membership of seventeen, he said, included all the regular physicians of Newport except one or two.

DR. C. H. PARSONS, *Chairman of the Trustees of the Fiske Fund*, reported briefly as to the investment of the same.

The following gentlemen were then elected

OFFICERS FOR THE ENSUING YEAR:

President.—Job Kenyon, M.D.

Vice-Presidents.—O. C. Wiggin, M.D., and H. G. Miller, M.D.

Secretary.—George D. Hersey, M.D.

Treasurer.—Chas. H. Leonard, M.D.

Censors.—Drs. Ariel Ballou, Otis Bullock, J. H. Eldredge, Geo. P. Baker, J. W. C. Ely, Lloyd Morton, S. S. Keene, Benj. Greene.

The reports of delegates to other State Societies being in order, Dr. H. G. Miller responded as delegate to Massachusetts; Dr. W. S. Bowen to New Hampshire; Dr. Neil O'Donnell Parks to New Jersey; Dr. W. E. Anthony to Maine, and Dr. Browning to Connecticut.

The Chair presented a communication from the Secretary of the Newport Medical Society, accompanied by a draft of an enactment to be presented to the General Assembly of the State, providing for the

ABOLITION OF THE PRESENT CORONER SYSTEM

by so modifying it that only properly qualified persons can be appointed to the office of Coroner.

Several Fellows spoke with much earnestness on the subject, urging the need of change and reform in our present system, and citing instances from their present experience illustrative of the same.

The proposed Act, as now framed, provides for the establishment of the office of *Medical Examiner* and gives in detail the duties of the office. Section I. abolishes the office of Coroner altogether. Section II. provides for the election by the General Assembly of able and discreet men in each county, learned in the science of medicine, who shall be between the ages of twenty-five and forty-five years, to be medical examiners. Section III. regulates the number of examiners for each county. The remaining clauses of the Act, as framed, relate to the time for which such examiners shall hold their office, amount of bond required, fees, manner of examination, expenses, subpœnas for witnesses, duties of trial justices, etc., thus so entirely changing the law bearing on coroners and their duties as to admit of the appointment of none but regular practitioners of medicine, and to preclude all possibility of concealing the crime of murder or evading punishment for endangering human life.

It was voted to appoint by ballot a committee of three Fellows, to whom the subject shall be referred for consideration and modification if necessary, with instructions to report on the same at the next quarterly meeting.

The committee elected were the following: Dr. Ariel Ballou, of Woonsocket: Dr. Samuel W. Francis, of Newport; and Dr. James H. Eldredge, of East Greenwich.

It was also voted that two hundred copies of the proposed enactment be printed for the use of the Society.

It was then voted that the next quarterly meeting be held at Newport.

The President, DR. KENYON, then read his *Annual Address*. It was a thoughtfully written paper on the subject of "Rational Therapeutics," and received the close attention of the Society for the twenty minutes of its delivery.

The meeting then adjourned to Spink's Hall, where the annual dinner was served, Dr. S. W. Francis acting as Anniversary Chairman.

MINNESOTA STATE MEDICAL SOCIETY.

Fifteenth Annual Meeting held at Minneapolis, June 19 and 20, 1883.

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, JUNE 19TH, FIRST DAY.

MORNING SESSION.

THE Society was called to order by the *President*, DR. P. H. WILLARD, of Stillwater.

After the usual preliminary exercises, DR. MCMURDY, of Minneapolis, extended a hearty welcome to the Society on behalf of the city and of the medical profession, and he was followed by the *Chairman of the Executive Committee*, DR. KIMBALL, of Minneapolis, who set forth the order of business adopted, and then, in the name of the physicians of Minneapolis, invited the Society to make an excursion after its adjournment to Lake Minretonka, and to a banquet at the Hotel Lafayette, at that favorite watering-place.

About forty applicants for membership were, upon recommendation of the Committee on Credentials, elected by the Society.

THE LIBRARY AND MUSEUM OF THE SURGEON-GENERAL'S OFFICE.

DR. TALBOT JONES, of Saint Paul, introduced the following resolutions, which were unanimously adopted:

Whereas, The collections known as the Army Medical Library and Museum of the Surgeon-General's Office, Washington, D. C., are the most extensive and

valuable in America, and are unequalled even in Europe, and as their usefulness to the medical profession is very great, as is evidenced by the many years spent in their collection, by their emphatic endorsement by the said profession, and by the anxiety evinced lest they should be injured or destroyed; and

Whereas, This valuable collection is now placed in a building altogether inadequate to its proper care and protection, and is constantly in danger of being destroyed by fire, which would cause an irreparable loss to the profession throughout the country; therefore

Resolved, That the Minnesota State Medical Society, recognizing the inestimable value of the Army Medical Library and Museum, believe that Congress will meet the wishes of the medical profession of the United States by making an appropriation sufficient to provide a fire-proof building suitable, as regards security and size, to accommodate the collections; and they are respectfully but earnestly urged to make such an appropriation.

Resolved, That a copy of these resolutions be sent to each senator and representative of our State, and that they be urged to use all their influence in bringing the matter before Congress, and in securing favorable action in the premises.

AFTERNOON SESSION.

Upon reassembling in the afternoon the President delivered

THE ANNUAL ADDRESS,

in which the Society, while congratulated upon its *esprit de corps* and devotion to the highest interests of the medical profession, was reminded that the standard of professional excellence is high, and that efforts for its maintenance should not be relaxed. Reference was made to the act regulating the practice of medicine, which was adopted by the Legislature last winter; confidence in its efficacy was expressed, with the conviction that its operation would prove both effectual and beneficent in exposing and expelling pretenders, and in protecting legally qualified physicians as well as the public at large. Some notice was given to antisepsis as a surgical method as resorted to in Great Britain and on the Continent, but Listerism in all its minute details was not commended. Finally, attention was directed to the labors of Koch and others in the field of mycology, and to the importance both to pathology and therapeutics of the results that may be anticipated.

THE REPORT OF THE COMMITTEE ON MEDICAL EDUCATION,

was presented by the *Chairman*, DR. HEWITT, Secretary of the State Board of Health. It was chiefly an appeal to the members of the Society to lend their influence to secure a more thorough training of the student, especially as preparatory to his attendance upon lectures; and the opinion was expressed with warmth, that the degree of M.B. should precede that of M.D., as no man can be truly called *doctor* until he has acquired, by experience, the qualifications and ability to teach others.

Occasion was taken to comment at length upon the new law regulating the practice of medicine in Minnesota, whose most important provisions are, briefly, as follows: A faculty of five physicians is elected by the Regents of the State University, comprising Chairs of Anatomy, Practice, Surgery, Materia Medica, and Obstetrics [the gentleman to whom the latter Chair has been assigned represents the homœopathic school]. The functions of the faculty are purely those of an examining Board; whatever may be done hereafter in organizing a medical department of the University as a school, at present it is not intended that the faculty shall be teachers. All physicians and persons practising medicine, of whatever creed or school, are required to present their diplomas to the faculty, and its members are empowered to decide which schools shall receive recognition and which shall not. All who possess credentials satisfactory to the Board, are enrolled as legally qualified to pursue their calling; others are required to pass an examination, which, if accomplished, entitles them to a license to practise, but if not, makes them liable to penalties should they continue to pursue the profession of a physician. The foregoing relates to all physicians the minimum period of whose residence in the State has been five years: those who have become residents within that time must pass an examination, without regard to the validity of their credentials: upon compliance with this requirement, if successful, a license to practise is issued, even though the applicant be not a graduate. Presentation of bogus diplomas is made equivalent to forgery, and, constituting a criminal act, is punishable by severe penalties.

It is believed that the enforcement of the law will eventually be of value in thus plainly designating those who are entitled to the confidence of the community; and the separation of the offices of teaching and examining is regarded as a step which must sooner or later be taken wherever medicine is taught.

A Case of Leprosy, in the person of a young Norwegian, was exhibited to the Society by Dr. Stone, and excited much interest.

THE COMMITTEE ON PRACTICAL MEDICINE

presented a report through its *Chairman*, DR. ABBOTT, of Minneapolis, who dealt mainly with croup and diphtheria; the question of their identity, their etiology, pathology, and treatment: the report closed with an able and carefully prepared paper by Dr. Abbott, upon tracheotomy and its value as a remedial measure in acute laryngeal disease. The report, embracing citations of cases, was discussed with much interest; an animated debate occurring upon the question whether it is always practicable to differentiate with certainty, follicular tonsillitis, and diphtheria. A case had been reported of a child, suffering apparently from an ordinary attack of the former affection, in whose mouth and fauces no membrane could be discovered, and who, though discharged from treatment after three days, was attacked in about a fortnight by paralysis clearly of diphtheritic origin, and which proved rapidly fatal; *i. e.*, within a month from its commencement. The question was raised whether there are not cases of diphtheria analogous to those of the exanthemata in which the eruption seems to be absent; diphtheria without the membrane, yet manifestly diphtheria. As regards tracheotomy, the usual difference of opinion prevailed; some advocating it in every case, regardless of type, in which laryngeal stenosis occurs to an extent sufficient to cause even moderate dyspnœa, and others affirming that it should be limited to cases in which no pronounced toxæmia exists, as this in their opinion would contraindicate the operation.

DR. WHEATON, of St. Paul, *Chairman of the Committee on Surgery*, read a paper

ON SHOCK,

in which, after dwelling upon its pathology, he deprecated the practice of primary amputation after railway injuries, and maintained that the operation should not be performed until the period of reaction arrives. In the ensuing discussion, this view seemed to be entertained by the Society, though there was some difference of opinion as to the agency of psychical influences in the production of shock.

Reports were received from various committees. That upon Diseases of Children, by DR. OWENS, dealt with

DIPHTHERIA.

A firm belief in the germ origin of the disease was expressed, and the internal administration of iodine and carbolic acid recommended as a treatment both logical and effectual. The debate which followed revealed the usual diversity of views; some contending for and some against the local origin of the malady, while others held that it may be either local or general in its mode of invasion. So, also, the value of albumen in the urine as an element in prognosis was denied by some and upheld by others.

The report of the Committee on Obstetrics, by Dr. Lincoln, included the relation of cases of dystocia and of placenta prævia, with their management.

On motion of the *Treasurer*, DR. SHEARDOWN, it was ordered that an honorarium of two hundred dollars be presented to Dr. Boardman, in acknowledgment of his services as Secretary; he having discharged the duties of the office for several years without compensation.

WEDNESDAY, JUNE 20TH, SECOND DAY.

DR. HUNTER, of Minneapolis, a pupil of Lister, exhibited to the Society a *Case of Compound Fracture of the Ankle*, and in their presence applied dressings in accordance with the tenets of the illustrious apostle of antisepsis.

It was ordered that the *Northwestern Lancet*, published in St. Paul, be made the official organ of the Society.

THE ANNUAL ESSAY,

by DR. RIGGS, of Saint Paul, had for its theme Functional Nervous Disease, and, more particularly, Neurasthenia. In this paper the statement was made that Minnesota is more productive of this class of neuroses, in proportion to her brain-working class, than any other State in the Union; and that, as a result of our climatic environment, we are more sensitive to heat and cold than foreigners. Galvanization of the brain and superior ganglion of the cervical sympathetic was recommended as useful in brain-exhaustion; and, in the insomnia so frequently attendant upon functional nervous disease, the writer affirmed that no measures are comparable with galvanism and frequent feeding during the night. The bromides, chloral, opium, and alcohol should seldom be used, since galvanism, careful nutrition, and massage will, in a more successful manner, meet the exigencies of the case. In the speaker's experience, galvanism is infinitely superior to faradization in the treatment of functional nervous disease, notwithstanding the statements of Beard and Rockwell to the contrary. In some cases, static electricity was held to be of value.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—Dr. W. L. Lincoln, of Wabashaw.

Vice-Presidents.—Dr. E. J. Davis, of Mankato; Dr. Jas. Davenport, of Saint Paul; Dr. R. L. Moore, of Spring Valley.

Treasurer.—Dr. S. B. Sheardown, of Stockton.

Recording Secretary.—Dr. C. H. Boardman, of Saint Paul.

Corresponding Secretary.—Dr. Clara E. Atkinson, of St. Paul.

Dr. Fenger and Dr. C. T. Parks, of Chicago, and Dr. Ayres, of Omaha, were elected *Honorary Members.*

The usual complimentary resolutions were adopted, and the Society adjourned, to meet in Stillwater on the third Tuesday of June, 1884.

NEWS ITEMS.

NEW YORK.

(From our Special Correspondent.)

THE CODE AND THE RESULTS OF THE POLL OF THE PROFESSION IN NEW YORK STATE.—The Council of the New York State Medical Association for upholding the National Code of Ethics, reports the progress made in the canvass which has been undertaken to ascertain the views of the profession of the State on the subject of the Code of Ethics, as follows: A circular has been sent to each member of every county society, and also to many who are not members of county societies. Two thousand two hundred and fifty-six affirmative replies have already been received. The number is increasing daily. In the city of New York alone, upwards of seven hundred medical gentlemen have signified in writing their adherence to the National Code, and their names are appended to this report. Many in this and other counties are still silent, and these are earnestly appealed to for a speedy answer, as it is desired that the vote of every member of the regular profession be given on this question.

The subjoined exhibit gives, by county, the number of those who are in favor of the National Code. Many county societies known to be loyal have not yet sent in their full quota.

Number of Physicians, in each County of the State of New York, who uphold the National Code of Medical Ethics.

Total, for the whole State, to June 21, 2256.

The above exhibit indicates how each county now stands, and what the chances are for an increase of the majority for the National Code.

The Council having canvassed all sides, beg leave to report that six hundred and thirty-nine (639) in the whole State have declared themselves in favor of the "New Code," and two hundred and five (205) in favor of no code; of these latter, many say, "no Code rather than the New, but if there is to be a Code let it be the

National." More than twenty-two hundred (2200) in this State say, "there shall be a Code, and that Code shall be the National." This clearly shows that the National Code is now sustained by a very large majority, and there is every reason to believe that this majority will soon be greatly increased.

To some objections which have been received, the Council replies that the purpose of the Code is not directly to combat quackery, but to regulate the conduct of physicians toward irregular practitioners, as well as toward each other and toward the public; that the approval of the Code has nothing to do with penalties for the non-observance of its rules, and that the institution and enforcement of penalties belong exclusively to local societies. Admitting frequent violations of the Medical Code, it is no more to be abrogated on that account, than other moral precepts which are not observed by all, or which are not rigidly enforced. The members of the Council have strictly abstained from appeals to the public in regard to the unfortunate discussion now existing in this State on the subject of the Ethical Code. They have not permitted themselves to be interviewed; they have not, directly or indirectly, furnished communications for newspapers, nor have they assailed the motives of those who have been active in efforts to establish an important alteration in the Code. They believe that peace and harmony cannot exist in the profession until the "New Code" advocates cease their agitation, put an end to the disturbance which they have created, and quietly submit to the will of the majority. The result of the present canvass, as far as it has progressed, plainly shows that the profession does not sustain the "New Code," but desires the reënactment of the National, which should be the only Code of Medical Ethics in this and every State of the Union. That this is the sentiment of the medical profession throughout the land—North, South, East, and West—no one can doubt.

In the *New York Herald* for June 6th it is stated that the New Code advocates have also published a pamphlet report of their canvass, from which we extract the following statement:

"The subscriptions to the New Code now reach 1265. They are drawn from the different counties in number as follows:

COUNTIES.	Nos.	COUNTIES.	Nos.
Albany	19	Onondaga	11
Allegany	7	Ontario	7
Broome	8	Orange	7
Cattaraugus	4	Orleans	2
Cayuga	10	Oswego	10
Chautauqua	7	Otsego	8
Chemung	8	Putnam	1
Chenango	8	Queens	5
Clinton	2	Rensselaer	5
Columbia	5	Richmond	6
Cortlandt	2	Rockland	5
Delaware	6	St. Lawrence	13
Dutchess	15	Saratoga	3
Erie	19	Schenectady	7
Essex	1	Schoharie	7
Franklin	6	Schuyler	4
Fulton	4	Seneca	3
Genesee	5	Steuben	23
Greene	4	Suffolk	2
Herkimer	4	Sullivan	2
Jefferson	12	Tioga	5
Kings	73	Tompkins	7
Livingston	9	Ulster	7
Madison	8	Warren	4
Montgomery	5	Washington	7
Monroe	22	Wayne	7
New York	251	Westchester	7
Niagara	2	Wyoming	1
Oneida	12	Yates	1

"The total number of signers in the report is 1265,[1] but it was understood several days ago that over one hundred more had subscribed, and the list has been increased since then. The total membership of the County Medical Societies is 3,827, so that the liberals thus far have only captured a large one-third. They say that the Old Code men have only obtained about six hundred signatures up to date, and that the remainder are non-committal as yet."

PHILADELPHIA.

JEFFERSON MEDICAL COLLEGE.—At a meeting of the Board of Trustees, held last Monday evening, Dr. Theophilus Parvin, of Indianapolis, was elected to the Chair of Obstetrics and Diseases of Women and Children, rendered vacant by the resignation of Prof. Wallace.

Dr. Parvin was born in Buenos Ayres in 1829, acquired a liberal education at the State University of Indiana, and received the degree of M.D. from the University of Pennsylvania in 1852. He has had considerable experience as a teacher, having held professorships in the Medical College of Ohio and in the College of Physicians and Surgeons of Indiana, and is now Professor of Obstetrics and Medical and Surgical Diseases of Women in the University of Louisville. He was President of the American Medical Association in 1879.

Dr. Parvin is widely known as a learned and scholarly writer, and enjoys a high reputation as a lecturer and teacher. He is at present engaged in writing a systematic work on Midwifery, which, we understand, will appear shortly. His election is regarded with great satisfaction by the friends of the school.

NEW ORLEANS.

(*From our Special Correspondent.*)

SUMMER is well upon us, and although the thermometer has not ranged very high, the suffering from heat has been very great and general. The cause of this is the excessive relative humidity. On June 8th, at 2 P. M., the relative humidity was 90, while the temperature was 87.4°. Total rainfall for week ending June 9th, 4.51 inches. There were two cases of sunstroke for week ending June 16th. The temperature of one of the cases was 109.5° in axilla just before death.

SMALLPOX, strange to say, still has its own way. Deaths for week ending June 9th, 33 colored, 12 white. The fight against it is open to criticism. The Board of Health still refuses coöperation with the Auxiliary Sanitary Association in any and all matters. Deaths for week ending June 16th, 27 colored, 17 white.

One of the cases of leprosy—a woman—in the hospital broke out on May 15th with smallpox. Several instances have occurred in which persons have entered the hospital with a fever which afterwards proves to be that of the stage of invasion of smallpox. She probably became infected from one of these cases.

MALARIAL FEVERS are coming rapidly to the front. Under the warmth of the June sun and the rains, the poison is rapidly generated in the swamps which surround New Orleans. Last week, ending June 9th, there were six deaths from malarial fever, five being called congestive. It is interesting to note how largely the term *congestive* figures in the mortuary reports from this section of country. While it is reasonable to conclude that the influence of malaria and the effect of heat in enervating nerve function, should render the occurrence of congestion a more frequent event in warm latitudes than in those which are more temper-

[1] [*Sic*, actual count shows 715.]

ate; there is still reason to believe that it is less often a cause of death than the local statistics would show.

THE NATIONAL BOARD OF HEALTH INSPECTION SERVICE began May 15th, and will continue until June 30th, when its funds expire. If no other good is done by it, certainly the prevention of sensless shotgun quarantines should be appreciated. Should a rumor of yellow fever in New Orleans be started, and no responsible inspectors certify to the non-infectiousness of passengers and goods per railroad and steamers, trains will be compelled to pass stations at full-speed, and steamers be prevented from landing at any little town which may become panic-stricken. Of course, such rumors are liable to be started at any time, but the officers of all the health organizations here are pledged to report any true or suspicious case as soon as discovered; and credence should be given to them, and not to every idle report prompted by malice or otherwise.

YELLOW FEVER.—No case has been reported yet. Not so very many years ago—indeed, not more than twelve years—doctors vied with each other as to who would have the first case of yellow fever. It was a big thing to report the first case; almost as much so as to report the greatest number. Now a doctor shuns the trials and tribulations attendant upon the diagnosis of the first case, and the gossip and criticism which meet him on every side.

THE ODONTOLOGICAL SOCIETY had its annual meeting and dinner last week: both a success.

BERLIN.

(*From our Special Correspondent.*)

VIVISECTION BEFORE THE GERMAN DIET.—The editorial in THE MEDICAL NEWS of May 26th, recalls to mind the strange fact that the antivivisectionist agitation has made remarkable progress even in Germany. Petitions, systematically organized all over the country, were brought before the German Diet. The Petition Committee proposed a simple Order of the Day, since no evidence was given of any real mischief, and since the House would confide in the government instantaneously restraining every abuse in the future. But notwithstanding that the Secretary of State for Public Instruction himself made a long and able speech in favor of scientific vivisection, in the session of April 16th, the House resolved, by a slight majority, to recommend the petitions to the Government for consideration.

HUMBOLDT MONUMENT.—By erecting the statues of Alexander v. Humboldt and his brother Wilhelm in front of the University, the government and the metropolis have fulfilled a long-felt duty. The eulogium upon Alexander, was made by Professor Virchow, who dwelt upon the pains-taking energy of the great naturalist.

DR. HENRY J. BIGELOW.—At a meeting of the Royal Medical and Chirurgical Society of London, held on June 12th, Dr. Henry J. Bigelow, of Boston, was elected a Foreign Honorary Fellow, as were also Prof. Charcot, of Paris, Prof. DuBois Reymond, of Berlin, and M. L. Pasteur, of Paris.

THE ASSOCIATION OF MEDICAL SUPERINTENDENTS OF AMERICAN INSTITUTIONS FOR THE INSANE met at Newport on Tuesday. Dr. J. H. Collender, of Nashville, presided. The following officers were elected for the ensuing year: President, Dr. John P. Gray, of Utica, N. Y.; Vice-President, Dr. Pliny Earle, of Northampton, Mass.

WHAT THE HOMŒOPATHISTS THINK OF THE NEW YORK CODE.—*The New York Tribune* has been interviewing prominent homœopaths to ascertain their views on the controversy in reference to the Code now going on in New York, and finds that they regard it with "perfect equanimity and undisguised amusement," and that they spurn the idea of their abandoning the "law of similars."

Dr. S. P. Burdick, who is a professor of obstetrics in the Homœopathic Medical College, thus expressed himself to the *Tribune* reporter: "There is no doubt at all that the consideration that led to the adoption of the New Code was largely pecuniary. The homœopaths, as a rule, have carried with them a clientage that represents the largest amount of money. The result has been that, with our advance, specialists have grown up in our school as clear-headed and successful as those of the old school, if not more so. We have reached a point where in no branch in the practice of medicine, surgery, or obstetrics are we obliged to go out of our own ranks for the best aid and counsel. That, I suspect, has dawned on their minds, and they have come to see that they have kept themselves out of a great deal of lucrative consultation practice which might have fallen into their hands if they had treated us with decent consideration. Of course, we enjoy their controversy now. We never asked for their consultations, and their refusal to consult with us never gave us the slightest discomfort, for the reason that we have been able, with truth in our hands, to work without them. We have the kindliest of feelings toward our brother-practitioners on the other side, and I for one will only be too happy to extend to them any advantage that I can in opening up the great field of truth, believing as I do that in the healing art there should be only one sentiment in the minds of those that practise it, namely, to grasp everything and anything that looks toward the benefit of sick and suffering humanity. When anything presents itself that is in advance of homœopathy, I will be one of the first to accept it."

HEALTH IN MICHIGAN.—Reports to the State Board of Health, for the week ending June 16, 1883, indicate that intermittent fever has increased, that pneumonia has considerably decreased, and that erysipelas, bronchitis, cholera-morbus, diarrhœa, measles, inflammation of the brain, rheumatism, and whooping-cough have decreased in area of prevalence.

Including reports by regular observers and by others, diptheria was reported present during week ending June 16, and since, at twelve places; scarlet fever, at twenty-one places; and measles, at twenty-six places; smallpox was reported in Kalamazoo Township, Kalamazoo Co., (seven cases) June 16. The last case in Lyons Township, Ionia Co., died June 11.

A correspondent at St. Joseph, Berrien Co., writes: June 12, 1883, that paralysis is the most prevalent disease in that locality, attacking persons at all ages, but especially the young, and seems largely due to preceding intermittent fever, convulsions, and hydrocephalus.

OFFICIAL LIST OF CHANGES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 18 TO JUNE 25, 1883.

BIART, VICTOR, *Captain and Assistant Surgeon.*—Assigned to duty as Post-Surgeon at Fort Lisseton, D. T.—*Par. 1, S. O. 102, Department of Dakota, June 13, 1883.*

GORGAS, W. C., *First Lieutenant and Assistant Surgeon.*—The leave of absence granted in Par. 5, S. O. 51, c. s., Department of Texas, extended one month.—*S. O. 63, Military Division of the Missouri, June 19, 1883.*

WYETH, M. C., *First Lieutenant and Assistant Surgeon.*—Assigned to duty at Fort Maginnis, M. T.—*Par. 2, S. O. 103, Department of Dakota, June 14, 1883.*
